In the hunting heavy norse; moving through a gate which closes too quickly and faid to sepress an action in the grant post, and couses too quickly and lag just inside the stifle joint against the gate post, densities madella to be forced outwards, with the immediate result dring the horse incapable of moving forward, although it is d ignorms and notes him to a shed or shelter of some kind, possible, with care, to lack him to a shed or shelter of some kind,

brehe may stand until his injuries are attended to.

To a sailful veterinarian the reduction of the cislocation of the To a same to difficulties. With the aid of a side line, the bind tate in the strawn forward by an assistant while the operator applies into a may a contract of the displaced bone to push it upwards and inwards preserve against the place. The side line is then relaxed, but suffinational superior representation to keep the leg in a forward position for continuous is maintained to keep the leg in a forward position for some time, in order that the strained ligaments may to some extent worst then tone. If possible, the horse should be kept quite quiet mover amount where reduction of the dislocation has been effected for hants four hours, or be moved to a more convenient place in a proper mb, if one can be obtained.

Sprain of the ligaments of the stifle joint is an accident of many

degrees, depending on the amount and direction of the force cmployed. There are ligaments which hold the lower condyles of the thigh bone on to the interrticular cartilages, which rest on the bone below (tibia); also liaments which keep the cartilige in place, and several ligamentous bands attaching the knee no (patella) to the articular surbetween the lower condyles the femur. In an ordinary prais, any or all of these may mier, and, as a rule, the symplous do not enable the examiner b define the exact position of the

VETERINARIAN NOTES AND QUERIES.

BOTS IN HORSES.—"Derg" would do well to consult the books on Veterinary Homosopathy, by J. Moore, V.S., "Horses Well and Ill," 3s. 6d., and by R. P. G. Lord, M.R.C.V.S.L., "The Vare Mecum," 15s. The Homosopathic Trituration of Arsenicum Alb. can be used as directed without the possible risks attending the employment of the crude white arsenic. Either work can be obtained from the Homeeopathic Publishing Company, 12, Warwick lane, Paternoster-row, E.C.-House.

DESTRUCTION OF LARVE OF THE BOT FLY.-With reference to the discussion which your correspondent "Derg" is vites on the subject of "Bots in Horses," it may be vary interesting to speculate on the nature of the parasitss and the means of expelling them from the intestines of young horses. I should like, however, to hear the opinion of your correspondents as to the means of destr ying the larvae on the pastures, and what the effect of a strong dressing of gas lime would be towards the attainment of this object. I have a very high opinion of gas lime as a fertiliser of immense capabilities, and I think it is a destroyer of insect life, and would possibly be found fa al to the fly deposits mentioned by "Derg." I would suggest two tons to the acre on his pastures in November, and a diessing of waste salt in March or April, The products of coal, too, have wonderful properties, as, for instance, the Thorncliffe sheep dip, which is said to destroy microbes, and to be harm'ess to the animal internally. I may say that I have no interest in the sale of any of these commodities.—PREVENTION.

THE NATURALIST.

BURCHELL'S RHINOCEROS

IN THE LAST NUMBER of the Field I had the satisfaction of giving an account of Mr Coryndon's capture of two specimens of the Rhinoceros simus. The engraving now presented is from a photograph of one of the spec mers that belonging to the Hon. Walter Rothschild-which has been set up by Mr Rowland Ward. As I mentioned last week, this example is regarded by Mr. Coryndon as being most naturally mounted. Mr Coryndon's own account of the capture of these two animals was published in the last number of the Field, but a faller description of the habits of the species was given by Mr Selous in a paper communicated to the Zoological Society in 1881. Mr Selons was hunting in South Africa early in the seventies, when rhinoceroses were plentiful, and he had many opportunities of observing the babits and peculiarities of these animals. He maintains, in opposition to many later writers, that there are but two distinct species of rhinocereses in that district namely, the R. simus, and the smaller prehensile lipped R. bicornis. The first feeds on grass, and the second on bush. The square-

such as the northern sea cow (Rhytina), have been exterminated, so that there can be but little hope for terrestrial , pocies unless it is the direct interest of each individual hunter to stay his hand. W. B. TEGETMEIER.

PROTECTION OF BIG GAME.

Sir, -As one who is much interested in the question of "preservation of big game," I have felt some surprise that, although numerous complaints are constantly appearing in print about the needless and cruel destruction of wild animals, few practical propositions are put forward for protecting the miserable remnant that still survives.

I have seen the following suggested as regards South Africa: "That a number of sportsmen join together and acquire from Government a suitable tract of land for the preservation and breeding of wild animals in or near their native haunts. This would necessitate some capital, and the organisation of a number of keepers. both native and British. This was thought likely to become a good paying concern, that it would afford good shooting to the members. and that young animals could be yearly caught for sale to the European menageries." The objection to this seems to be the distance from England, the time on the journey, and that most men, except a favoured few, would not care to risk their money in a concern so far off, and which they could only hope to visit at few and distant opportunities.

I have often thought, especially when I see the money and time devoted to such comparatively insignificant and uscless animals as some of the fancy dogs, for whose sake shows, clubs, weekly papers, &c., are being devoted, that were anyone to start a practical scheme in connection with big game, there would be many sportsmen and naturalists who would come forward and assist.

We have herse, cattle, and canine societies, bird, rabbit, and even cat clubs, why not a big game protection scriety? There is not the slightest doubt—indeed, it has often been proved—that many species of big game are quite capable of domestication, and of bringing in good returns in cash; further, they can be made to do so in this country, which is a great point.

I believe I am right in stating that two species of big game stand out ahead of all others in this respect-viz., the bison and the eland. The tameness of these brasts equals that of domestic cattle; they thrive and breed well in England, and their young are in good demand, and command very handsome and remunerative prices. Why not form the club, and start the enterprise with the above two species? afterward more could be added.

The wapiti would be a most suitable beast. I have some doubts whether the moose could be successfully bred and reared on small farms. It would, however, be well worth trying to save this, the finest species of the deer tribe, and one which, if it cannot be kept

domesticated, is sure of a speedy yet silent destruction.

I should propose taking a farm of some 500 agres, or less, to start with, in one of our distressed agricultural districts where land is cheap and with the necessary buildings upon it. Most of the

land could be put into grass and all real farming eschewed, except the buying of a craple of breeding mares to do odd jobs and plough up a few acres for roots and corn. which is all that would be necessary. Enough rabbits should be trapped to nearly pay the rent, or they could be kept for shooting purposes; and, if the locality were well chosen and the ground game and birds looked after, some good sport should be forthcoming.

I have myself travelled in Africa, and understand well where to go for, and all costs connected with importing, a small herd of elands. As to hison, they are, I

welling, and pain in the injured part will also be some guide to the entent of the injury, and with the evidence the observer must becoment in forming an opinion. Trainent of inflammation of he stille, whether it is due to a main, confusion, or wound, will be directed to the reduction d the inflammatory state as coolings possible, for the reason that the articular surfaces are internally liable to the ulcerative date. Fomentation with warm vater, larative medicine, and low detare the chief means to be Morted and the cessation of the scale symptoms is an indicathat they have been to some ettent effectual. But it is often observed that the lameness remains even when the joint has raumed its natural contour, and the heat and pain have apparately ceased. This continuance of lameness indicates beyond

mention the presence of disease in some of the joint structures, mid the multe impossible to determine on what changes of stracwe the defective action depends. There may be abrasion of the moval membrane when it is reflected over the edges of bones or taitlage or actual removal of cartilage, or death of a portion of bone probably underneath the articular surface. And the most experienced reluminan will not be able to satisfy himself as to which of these building exists; and from first to last the diagnosis must of nemativ he more or less doubtful, until a post mortem examination proves the opinion to be correct, or, it may be, quite wide of the

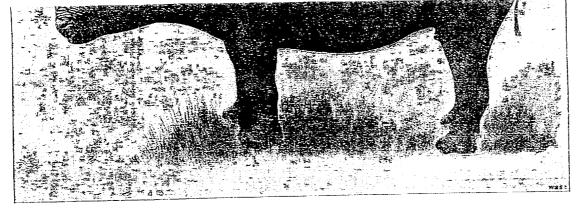

The experienced man will be assisted in his judgment by his obserbut and the degree of lameness, its increase or otherwise during the degree of lameness, its increase or otherwise during and the character of the animal's gait in walking and hoting and he will generally be in a rosition to advise as to the position is our being effected by treatment. In any case the homenan and his servants may rest assured that lameness of any and affecting the stifle joint is not a case for amateur dectoring, and the horse is not worth the cost of treatment by a competent tworld be a wise course to consign the animal at once to the kennela 👯

Velerinary authorities do not write hopefully of the treatment of the inntlameness, and it is not to be expected that any special tenedies should be advocated differing in any important details from hose in ordinary use, i.e., stimulating liniments, blisters, setcus, and an final resource, firing. In reference to the two last modes the finest blistering and the use of the actual cautery—it has been suggested that they both tend to keep the joint at rest by the relingand pain which they cause, rendering movement unpleasant to the animal, and difficult at the same time. Counter-irritation in by lominary be temporarily useful, or may remove a chronic irritabilly of the loint structures, but there is no form of treatment which an near the breaches caused by caries or ulceration. In most of the came of stille joint lameness which have come under our notice the course of events has been tolerably uniform.

In ordinary sprain or contusion of the joint, followed, as usually being by swelling, pain, and consequent lamentes, treatment by fonditations, lest, and careful dieting has been successful, as it smeally is in such cases in other joints. But when lameness has immediator the subsidence of the symptems of inflammation, the find result has seldom been favourable. The horse has been worked in the norm that the stiffness would pass away. Then various the norm that the stiffness would have a second mendation of mades liments, &c. have been tried on the recommendation of hinds, who have seen them do wonders; blisters, estors, and the hing ion have all been used without permanent benefit, and at last the many all been used without permanent benefit, and at last the work of incorrables. the mitorium and all been used without permanent beneath of incurables.

When the property animal has been relegated to the list of incurables. Meanin opportunity for dissection has been sflorded in cases such ay 1008 above described, it has been found that such alterations of dipting aristed as rendered cure impossible; and, had their premore been known, no one would have advised the adoption of treatment much much inevitably fail.

FIFTH SHEET.

BURCHELL'S RHINOCEROS (B. SERUS).

Africa forty years ago, and as Andersson and Chapman relate, they shot as many as eight of these an mals at a water hole in a night. In 1878 and 1880, Mr Selous found them still numerous in a small tract of country in North-Eastern Mashonaland; but he prognosticated their speedy extermination, which is rapidly approaching, and therefore his description of their habits will be read with interest as unlikely to be superseded by that of any future traveller. Mr Selous writes as follows:

The square-mouthed rhimoceros is a huge, ungainly looking beast, with a disproportionately large head, a large male standing fit, fin, at the shot der. Like elephants and buffalces, they lie askep during the heat of the cay, and feed during the night and in the cool hours of early morning and evening. Their sight is very bad, but they are quick of hearing, and their scent is very seen; they are, too, often accompanied by rhim cer-s birds, which, by running about their heads, flapping their wirgs, and selecthing at the same time, frequently give them notice of the approach of danger. When disturbed they go off at a swift trot, which soon leaves all pursuit from a man on foot far behind; but if chased by a horseman they break into a gallop, which they can keep up for some distance. However, although they run very swiftly when their size and heavy build is considered, they are no match for an average good horse. They are, as a rule, very easy to shoot on he research, as it one gallops a little in front of and on one side of them, they will hold their course, and come sailing past, offering a magnificent broadside shot, while under similar circumstances a prehensilelipped rhinoceros will usuall, swerve away in such a manner as only to present his hind quarters for a shot. When either walking or running, the square-monthed rhinoceros holds its head very low, its nose nearly touching the ground. When a small calf accompanies its mother it always runs in front, and she appears to guide it by holding the point of her horn upon the little animal's rump; and it is perfectly wonder ul to note how in all sudden changes of face, from a trot to a gallop, or rice rersi, the same position is always exactly maintained. During the autumn and winter months (i.e., from March to August) the square mouthed rhinceeros is usually very fat; and its meat is then most excellent, being something like beef, but yet having a reculiar flavour of its own. The part in greatest favour amongst hunters is the hump, which, if cut off whole and reasted just as it is in the skin, in a hole dug in the ground, would, I think, be difficult to match either for juiciness or flavour.

In this species the horns vary very much in different individuals, so that they cannot be taken as indicative of species. In a full-grown square-monthed rhinceres the anterior horn varies from 18 inches to over 4 feet in length, usually slightly curved, but sometimes it is grite straight, and the anterior part of it rubs the ground as the arimal walks along feeding, and is in some specimens robbed flat by the friction. Mr Selous says he never remembers having seen an anterior horn in a square-mouthed rhimoceros that was not pertially flattened in this manner. The square-mouthed rhinoceros rarely attacks man unless wounded, it is usually a most inoffensive animal.

It is not satisfactory to know that the advance of civilisation in Africa will inevitably tend to the total extinction of both species of rhinoceros, which will pass cut of existence as surely as the quagga has done. The perfection of arms of precision has sea ed the fare of m ny of the larger animals. Man, utterly impotent to create, is powerful to dettion. Even gigartic animals inhabiting the waters,

Deerle Bud offier streetobe again pay in England, but elands and bison certainly would. All cow calves should be kept, a hord book formed, two or more (if possible) distinct strains kept to prevent inter-breeding, and in a few years a fine and paying herd would be the result. Other animals could be taken up as opportunity occurred.

What a sight for lovers of nature if animals collected from different continents could be seen, naturalised and acclimatised. roaming at will on the waste land adjoining some of our outlying country farms. Some of the tropical animals would require housing and careful treatment in winter; but I do not think they would be more delicate than Jersey cattle. As regards wildebeeste and other antelope, it would be a question of some difficulty to know how to bring a herd of these

mouthed rhinocercs was very abundant in the western part of South | swift-footed and capricious animals under cover were severe weather coming on; however, it could be managed with a little trouble.

The British nation has had the credit of sending out most of the best hunters; let it also have the credit of trying to save from extinction, at least, those species of wild game which can be turned to good account and added to the list of valuable domestic animals. I fear that in Africa we can expect no legislation to stay the speedy extermination of game that is going on.

Suitable land in England is to be had, the animals are still to be H. D. P. had, where are the men?

It reems to us that the domestication of foreign big game in England is, for many ressons, quite impracticabe. It was attempted with a limited number of species (amongst others the eland) many years ago by an Acclimatisation Society, and signally failed. A more fessible plan would be to try and secure some adequate protection for these animals abroad. We understand that a committee, including several well known sportsmen, has already been formed for the purpose of considering a scheme by Capt. A. St. H. Gibbons for the letter protection of big game in S.E. Africa. The details of this scheme will be submitted for the consideration of Mr Cecil Rhodes, and on receipt of his reply we shall doubtless hear more about it .- ED.

ARRIVAL OF SUMMER BIRDS.

REPORTS continue to reach us from all parts of the country respecting the arrival of migratory binds. As many of these are merely repetitions of previous announcements, we do not reproduce them here, nor do we propose to notice species whose arrival has been already chronicled, unless the reports are confirmatory of unusually early arrivals, or actually antedate them.

CHIFF CHAYF .- March 10, Hendon, Middlesex (L. Buttress). WHEATEAR.-March 29, Herne Bay (John Young).

Burchell's Rhinoceros

In the last number of the Field I had the satisfaction of giving an account of Mr Coryndon's capture of two specimens of the Rhinoceros simus. The engraving now presented is from a photograph of one of the specimens - that belonging to the Hon. Walter Rothschild - which has been set up by Mr Rowland Ward. As I mentioned last week, this example is regarded by Mr Coryndon as being most naturally mounted. Mr Coryndon's own account of the capture of these two animals was published in the last number of the Field, but a fuller description of the habits of the species was given by Mr Selous in a paper communicated to the Zoological Society in 1881. Mr Selous was hunting in South Africa early in the seventies, when rhinoceroses were plentiful, and he had many opportunities of observing the habits and peculiarities of these animals. He maintains, in opposition to many later writers, that there are but two distinct species of rhinoceroses in that district, namely, the R. simus, and the smaller prehensile lipped R. bicornis. The first feeds on grass, and the second on bush. The square-mouthed rhinoceros was very abundant in the western part of South Africa forty years ago, and as Andersson and Chapman relate they shot as many as eight of these animals at a water hole in a night. In 1878 and 1880, Mr Selous found them still numerous in a small tract of country m North-Eastern Mashonaland; but he prognosticated their speedy extermination, which is rapidly approaching, and therefore his description of their habits will read with interest as unlikely to be superseded by that of any future traveller. Mr Selous writes as follows:

The square-mouthed rhinoceros is a huge, ungainly looking beast, with a disproportionately large head, a large male standing 6 ft 6 in at the shoulder. Like elephants and buffaloes, they lie asleep during the heat of the day, and feed during the night and in the cool hours of early morning and evening. Their sight is very bad, but they are quick at hearing, and their scent is very keen; they are, too, often accompanied by rhinoceros birds, which, by running about their heads, flapping their wings, and screeching at the same time, frequently give them notice of the approach of danger. When disturbed they go off at a swift trot, which soon leaves all pursuit from a man on foot far behind; but if chased by a horseman they break into a gallop, which they can keep up for some distance. However, although they run very swiftly when their size and heavy build is considered, they are no match for an average good horse. They are, as a rule, very easy to shoot on horseback, as, if one gallops a little in front of and on one side of them, they will hold their course, and come sailing past, offering a magnificent broadside shot, while under similar circumstances a prehensile-lipped rhinoceros will usually swerve away in such a manner as only to present his hind quarters for a shot: When either walking or running, the squaremouthed rhinoceros holds its head very low, its nose nearly touching the ground. When a small calf accompanies its mother it always runs in front, and she appears to guide it by holding the point of her horn upon the little animal's rump; and it is perfectly wonderful to note how in all sudden changes of pace, from a trot to a gallop, or viva versa, the same position is always exactly maintained. During the autumn and winter months (i.e. from March to August) the square-mouthed rhinoceros is usually very fat; and its meat is then most excellent, being something like beef, but yet having a peculiar flavour of its own. The part in greatest favour amongst hunters is the hump, which, if cut off whole and roasted just as it is in the skin, in a hole dug in the ground, would, I think, be difficult to match either for juiciness or flavour.

In this species the horns vary very much in different individuals, so that they cannot be taken as indicative of species. In a full-grown square-mouthed rhinoceros the anterior horn varies from 16 inches to over 4 feet in length, usually slightly curved, but sometimes it is quite straight, and the anterior part of it rubs the ground as the animal walks along feeding, and is in some specimens rubbed flat by the friction. Mr Selous says he never remembers having seen an anterior horn in a square-mouthed rhinoceros that was not partially flattened in this manner. The square-mouthed rhinoceros rarely attacks a man unless wounded, it is usually a most inoffensive animal.

It is not satisfactory to know that the advance of civilisation in Africa will inevitably tend to the total extinction of both species of rhinoceros, which will pass out of existence as surely as the quagga has done. The perfection of arms of precision has sealed the fate of many of the larger animals. Man, utterly impotent to create, is powerful to destroy. Even gigantic animals inhabiting the waters, such as the northern sea cow (Rhytina), have been exterminated, so that there can be but little hope for terrestrial species unless it is the direct interest of each individual hunter to stay his hand.

W.B. Tegetmeier.
