**Srivastav, A. and Nigam, P. 2010.** Indian National Studbook of One horned rhinoceros (*Rhinoceros unicornis*). Wildlife Institute of India, Dehradun and Central Zoo Authority, New Delhi.

*Published as a Technical Report of the CZA assignment for the compilation and publication of the Indian National Studbooks for selected endangered species of wild animals in Indian Zoos.*

## Acknowledgements

This Studbook is a part of the Central Zoo Authority, New Delhi, assignment to the Wildlife Institute of India, Dehradun, for the compilation and publication of studbooks of selected endangered species of wild animals in Indian zoos. The authors wish to thank the Central Zoo Authority for financial support and the opportunity to compile the National Studbook for One Horned Rhinoceros.

We are thankful to Shri. P. R. Sinha, Director WII for his guidance and support. We would also like to express our appreciation for the advice and support extended by Dr. V.B. Mathur, Dean Faculty of Wildlife Sciences, WII. The authors also wish to thank all the staff members of the Central Zoo Authority, specially Dr. B.K. Gupta, Evaluation and Monitoring Officer, Dr. Naeem Akhtar, Scientific Officer and Shri. Vivek Goyal, Data Processing Assistant, for their advice and support.

The help of the following Zoos holding One horned rhinoceros in India is gratefully acknowledged in compilation of the studbook data.

Assam State Zoo, Guwahati, Assam  
Alipore Zoological Garden, Kolkatta  
National Zoological Park, Delhi  
Nehru Zoological Park, Hyderabad  
Kanpur Zoological Park, Kanpur  
Lucknow Zoological Gardens, Lucknow  
Nandankanan Biological Park, Bhubaneswar  
Sanjay Gandhi Biological Park, Patna  
Bhagwan Birsa Biological Park, Ranchi  
Sepahijala Zoological Park, Agartala  
Thiruvananthapuram Zoo, Thiruvananthapuram  
Veermata Jijabai Bhosle Udyana, Mumbai

We also wish to thank Ms. Laurie Bingmann Lackey of ISIS for providing the SPARKS software. Her kind advice and timely help were of great help in compilation of this studbook. The authors express their gratitude and appreciation to Shri. Mukesh Arora, Shri Virender Sharma, Computer personnel and Ms. Mandakini Nautiyal, Technical Assistant for the assistance.

We also wish to express gratitude for all the faculty and staff members of the WII, for their help and encouragement.

# One horned rhinoceros: Biology and Status

## Taxonomy of One horned rhinoceros

<b>Kingdom:</b>	<b>Animalia</b>
<b>Phylum:</b>	<b>Chordata</b>
<b>Class:</b>	<b>Mammalia</b>
<b>Order:</b>	<b>Perissodactyla</b>
<b>Family:</b>	<b>Rhinocerotidae</b>
<b>Scientific Name:</b>	<b><i>Rhinoceros unicornis</i></b>
<b>Species Authority:</b>	<b>Linnaeus 1758</b>
<b>Common Name/s:</b>	<b>Gainda (Hindi)</b>

Based on their large body sizes (>1000kg) and diet, Elephantidae (elephants), Rhinocerotidae (rhinoceroses), Hippopotamidae (hippopotamus) and Giraffidae (giraffes) comprise the four major families of mega-herbivores. Rhinocerotidae along with Equidae (horses) and Tapiridae (tapirs) each feature an odd number of toes with the middle toe being bigger. These families are a part of the order Perissodactyla (uneven-toed ungulates). The systematic relationships between rhinoceros species have been inferred using morphological, behavioural, geographical and, to a lesser degree, genetic data. The living Rhinocerotidae includes four genera that encompass five species and eleven subspecies.

There are two African species, each within a monotypic genus: the white rhinoceros (*Ceratotherium simum*) and the black rhinoceros (*Diceros bicornis*). The remaining two rhinoceros genera include three Asian rhino species: the Indian (*Rhinoceros unicornis*), Javan (*Rhinoceros sondaicus*) and Sumatran rhinos (*Dicerorhinus sumatrensis*). Recent studies dispute whether or not the Assam and Nepalese Indian rhino populations represent two distinct subspecies. The Indian rhinoceros is larger than the Javan rhinoceros, these two species are grouped into the single *Rhinoceros* genus based on a combination of geography, similar morphologic characteristics and feeding habits and inhabit a variety of habitats ranging from dense lowland forests to open flood-plains. Phylogenetic analyses based on mitochondrial DNA data, also support the grouping of the Javan and Indian rhinos into a single genus.

## Biology

The one horned rhinoceros inhabits riverine grasslands of the Terai and Brahmaputra basins. The species prefers alluvial plain grasslands, but is also found in adjacent swamps and forests. The current populations are restricted to habitats surrounded by human-dominated landscapes, so that the species often strays into adjacent cultivated areas, pastures, and secondary forests. The one-horned rhinoceros is a grazer. They are associated with the water bodies for feeding, wallowing and resting. The diet includes mainly grasses, but also some fruit, leaves, shrub and tree branches, and cultivated crops. The species also utilizes mineral licks regularly.

Greater one-horned rhinos have a brownish-grey, hairless skin, which develops thick folds, resembling armour plating. Several prominent folds protect the neck. The skin has a maximum thickness of upto four cm; the subcutaneous fat is 2-5 cm thick and well supplied with blood, which helps thermo-regulation. Between the folds, around the stomach, the inner legs and the facial area, the skin is rather soft and thin. The tail lies embedded between the hind-leg folds. They weigh between 1,800 - 2,700 kg, shoulder height is 1.75 - 2 metres, and are 3- 3.8 metres long. Animals in the wild are in general lighter in colour than their captive counterparts. Greater one-horned rhinos have one horn, which is typically 20-61 cm long, and weighs up to three kg.

Females are sexually mature at 5-7 years of age; males at 8-10 years. Mating takes place throughout the year and there is no specific calving season. Their gestation period is approximately 16 months (465-490 days), and they give birth every three years. The interval between births ranges from 34–51 months. The birth weight ranges from 60-77 kg. A calf drinks on average 20-30 litres of milk per day and grows by 1-2 kg daily. They start nibbling / feeding on roughage at the age of 3-5 months and continue to suckle up to the age of 20 months. In the wild, youngsters are predated by tiger. Adults have no enemies other than humans. Calf stays with its mother for at least four years. Usually mother rhino keeps her calf away from other rhinos and is very aggressive. This period is crucial to new born calf as it is vulnerable to predation. The longevity or life span of a rhino in the wild is 30-35 years and in captivity 47 years. The

rhino wallows in lakes, rivers and temporary pools. Heat regulation and escape from flies is probably a major function of wallowing.

## **Behavior**

The one horned rhinos have an activity peaks in the mornings and afternoons and prefer to rest or wallow in pools during the hot noon. The preferred habitats are grasslands riverine mixed forests and their ecotones. Foraging activity is carried out mainly in the grasslands while the mixed forests are used for resting.

One-horned rhinos are usually solitary animals, except for females with calves. Males defend loosely defined territories, which may overlap with territories of several other males. These territories are used to protect resources and the stronger males have territories which are resource rich, the lesser males occupy peripheral territories which are relatively poorer in resources. The females keep moving in between these territories and mate with the dominant males. The territories keep changing seasonally as resource availability changes. Excellent habitat patches may support many animals together without competition.

Mud pools (wallows) are places of socializing for rhinos. Various individuals congregate during noon in the mud wallows. After wallowing they separate again. Wallowing assists in thermo-regulation by cooling the animals. The mud layer formed on the skin serves to keep ecto-parasites away.

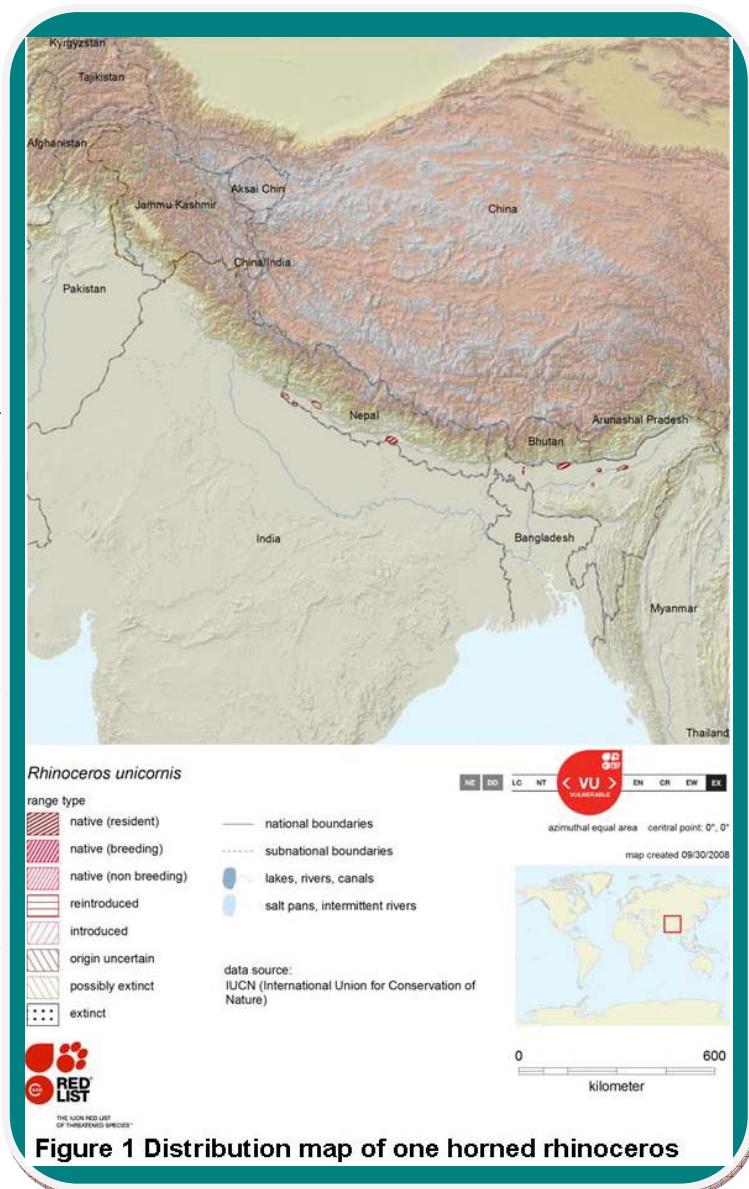

12 different sounds are frequently used for communication. Besides this dung heaps serves as communication points. One-horned rhinos prefer the use of same paths. These are scent marked by the secretions from the pedal gland of their feet, urine and dung. Several animals defecate at communal latrines. After defecating, greater one-horned rhinos rub their hind feet in the dung and continue to walk. By doing this they mark their own smell around the paths.

Mating in rhino is initiated by female which runs around the potential breeding male by making loud sounds and frequently squirting urine and occasionally pushing the male. The male rhino then takes over and chases female rhino for hours till the female rhino gets exhausted and stays in one place and mating then takes place.

## Distribution

The earliest recorded historical distribution of One horned rhinoceros in the Indian subcontinent was along the flood plains from northwestern Burma, across the Gangetic Plain, to the Indus River Valley in northern Pakistan. From the nineteenth century onwards land clearings fragmented their habitat and hunting reduced the populations. A consequence of this was the elimination of the species from all areas except the Chitwan Valley, lowland Bhutan, the Teesta Valley, West Bengal, and the Brahmaputra Valley in Assam.

The species is presently distributed in several pockets with large populations occurring in Kaziranga National Park, India and Chitwan National Park, Nepal and much smaller populations occurring in Pobitora, Orang, Jaldapara,

Gorumara and Manas Wildlife Sanctuaries in India and. Reintroduced populations exist in Dudhwa National Park, Uttar Pradesh, India and Bardia National Park and Sukhlapanta Wildlife Sanctuary in Nepal.

## **Threats**

Historically the major threats for the species were conversion of alluvial plain grasslands to agricultural lands and sports hunting. The present populations are threatened by poaching and decline in habitat quality.

Serious declines in habitat quality have occurred in some areas primarily due to

1. Invasion by alien plant species into grasslands.
2. Successional changes resulting in conversion of grasslands to woodlands and silting up of beels.
3. Grazing pressure of domestic livestock.

## **Status**

The population of Indian one horned rhinoceros was severely threatened in the last century. The population in the Brahmaputra Valley, Assam, reached a low of 20 individuals in 1908, when hunting was banned in the area of today's Kaziranga National Park. In the Chitwan Valley in Nepal, a strong population persisted until about 1950; then, poaching and land clearing reduced the number to approximately 60–80 survivors in 1962. This led to the species being categorized as endangered in the IUCN Red List of Threatened species. Since then the species has recovered due to strict protection and expanded into neighboring areas. This has led to a decrease in threat perception from Endangered to Vulnerable in the version 2009.1 of the IUCN Red List of Threatened Species. The species is listed in Schedule 1 of the Wildlife Protection Act (1972) Government of India and in CITES Appendix I since 1975.

## **Scope of the Studbook**

The present studbook of one horned rhinoceros has been compiled for the India region and the data used is current till July 31<sup>st</sup> 2009.

## **Methods Used**

The data collected for the compilation of the studbook by was way of field visits to collect the data from the concerned zoos and through mailed questionnaire surveys. The data collected was entered in SPARKS 1.54 and studbook report was generated using the reports option. The SPARKS software was used to create ~.prn and ~.ped files for demographic and genetic analyses by PM2000. PM 2000 was used to produce the census report, life tables and population projections, as well as founder statistics, inbreeding coefficients, possible pairings and population planning.

## **Status in Captivity**

The population status of the living one horned rhinoceros captive population in Indian zoos is presented below in table 1. There are 14 additional animals which have been transferred to zoos outside the country however; PM2000 uses these animals for analyses.

### Location Glossary

## **Population Planning/ Recommendations**

The species earlier listed as endangered in the IUCN Red List of Threatened Species has shown signs of recovery in the recent past, consequently it has been assigned to the vulnerable category in the 2009.1 listing. The decline in threat category is attributed to the recovery of populations in the Kaziranga and Chitwan National Parks. However, threats in other areas continue unabated also the population still occurs in fragmented pockets – a minuscule portion of its historic range. The maintenance of a genetically viable and demographically stable captive population is still an important component for the recovery of the species.

**Table 4 Genetic Summary Table:**

	<b>Current</b>	<b>Potential</b>
Founders	18	14 additional
Founder genome equivalents	7.18	26.96
Founder genome surviving	11.29	26.96
Gene diversity retained	0.93	0.982
Population mean kinship	0.07	0.018
Mean inbreeding	0.04	0.018
Ne / N	0.33	-----
% of pedigree known	91	-----

The Indian captive population is a part of the global effort towards this end. The captive population in India has 33 individuals distributed across 12 zoos. PM2000 has a total of 47 (26.21) individuals listed as alive in the studbook as it treats lost to follow up specimens as alive and a part of the population (14 animals listed as lost to follow up in table 3) which have been transferred out of the country. The total number of specimens in captivity across time in India is 135 (76.59.0). Of these 32 specimens are of wild origin and 18 of them have contributed to the gene pool of the captive population. The present population has high values for the various measures of genetic variability (Table – 4) and is suitable for further growth.

## **Management Goals:**

Population modeling of the captive Indian one horned rhinoceros was carried out using PM2000. Based on this analysis, it is envisaged that a population of 100 individuals to be achieved over a span of 10 years for the Indian captive population would allow the maintenance of a genetically viable and demographically stable captive population. The demographic and genetic management strategy for the

population is summarized in table 5. It suggests that with a population growth rate of 1.013 and a generation length of 17.5 years the population can achieve the target of 100 specimens in the next 10 years. The maintenance of the desired level of genetic diversity in the captive population can be achieved by the addition of 1 founder each for the next 10 years. This would allow the maintenance of 90% genetic diversity at the end of 50 years (Figure 2).

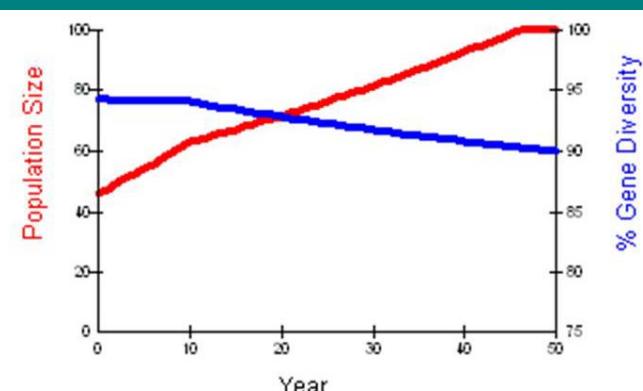

Figure 2 Demographic and genetic management strategy

**Table 5 Management Strategy Table:**

	Planned
Generation length	17.5
Population growth rate	1.013
Ne / N ratio	0.32
Initial gene diversity	0.944
Target population size	100
# New founders needed	1
Year to Stop Adding Founders	10
Years Between Addition Events	1
FGE Recruited per New Founder	0.40

**Generation length:** The average time elapsing from reproduction in one generation to the time the next generation reproduces. Also, the average age at which a female (or male) produces offspring. It is not the age of first reproduction. Males and females often have different generation times.

**Effective Population Size (Ne / N ratio)** -- The size of a randomly mating population of constant size with equal sex ratio and a Poisson distribution of family sizes that would (a) result in the same mean rate of inbreeding as that observed in the population, or (b) would result in the same rate of random change in gene frequencies (genetic drift) as observed in the population. These two definitions are identical only if the population is demographically stable (because the rate of inbreeding depends on the distribution of alleles in the parental generation, whereas the rate of gene frequency drift is measured in the current generation).

**Founder Genome Equivalents (FGE)** – The number wild-caught individuals (founders) that would produce the same amount of gene diversity as does the population under study. The gene diversity of a population is  $1 - 1 / (2 * FGE)$ .

Hypothetical pairings were carried out using the pairings options of PM 2000 from the ordered list of mean kinship of live individuals (table 6). The animals used for pairing are listed in table 7 and those not used for pairing are listed in table 8. In table 7, the column headed by “may be bred with” contains all those animals which can possibly be used for pairing. While the column headed by “may not be bred with”

contains animals which if used for pairing would produce inbred offspring. While carrying out the pairings due attention must be given to the facts that all founder animals get an equal chance of contributing to the gene pool and the animals have to be moved a minimal distance to implement such mating choices. Animals past their breeding age and animals that had been transferred out of India were excluded for pairing (table 8).

**Genetic Diversity (GD)** The heterozygosity expected in a population if the population were in Hardy-Weinberg equilibrium. Gene diversity is calculated from allele frequencies, and is the heterozygosity expected in progeny produced by random mating. The proportional gene diversity (as a proportion of the wild or source population) is the probability that two alleles from the same locus sampled at random from the population will be identical by descent.

**Mean kinship (MK)** The mean kinship coefficient between an animal and all animals (including itself) in the living, captive-born population. The mean kinship of a population is equal to the proportional loss of gene diversity of the descendant (captive-born) population relative to the founders and is also the mean inbreeding coefficient of progeny produced by random mating. Mean kinship is also the reciprocal of two times the founder genome equivalents.

## Demographic Analysis

### Census

The current captive population of one horned rhinos in Indian zoos dates back to 1944 when the first specimen, a female was brought into captivity. The first male entered the captive population in 1952 and the first captive birth was recorded in 1960, by 1969 there were 24 animals in

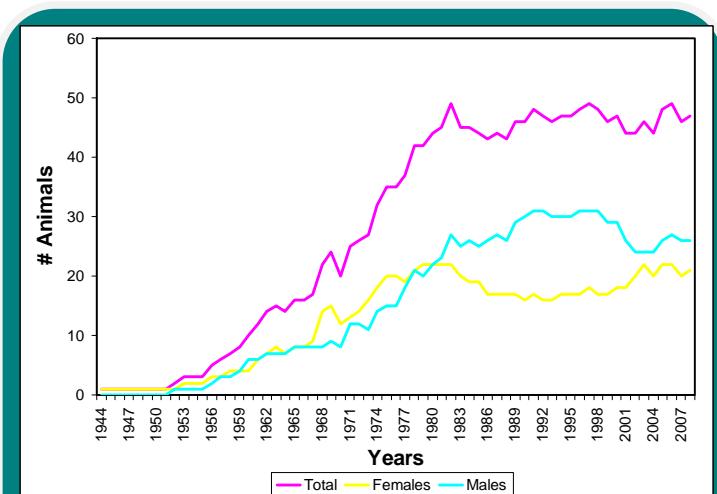

Figure 3 Total census of the Indian captive one-horned rhinoceros population

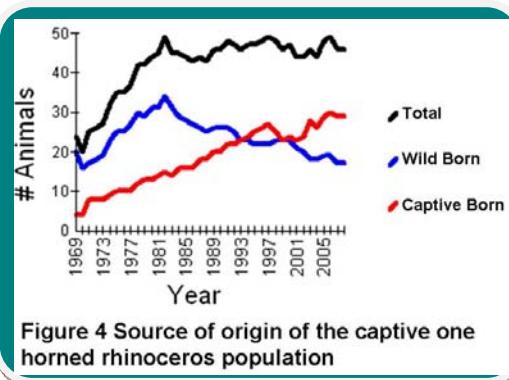

Figure 4 Source of origin of the captive one-horned rhinoceros population

captivity of which only 4 were captive born. In 1979 the total population had risen to 42 individuals of which 13 were born in captivity. The present population of rhinos is 33 in Indian zoos and a total of 47 out of which 14 specimens were lost to follow up due to their transfer outside the country.

## Age distribution

The age structure of the living population of one horned rhinoceros in captivity in Indian zoos was modelled using PM2000. The results obtained for stable age distribution (modelled data) suggest that the presence of individuals in each class is essential for a stable population. If rapid population growth is targeted then the number of individuals in the lower age classes should be

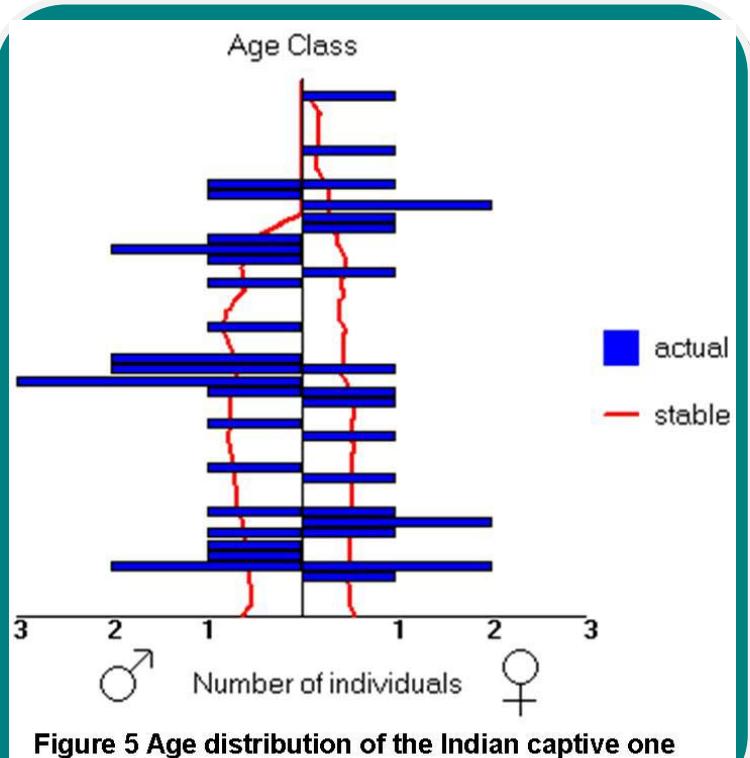

Figure 5 Age distribution of the Indian captive one horned rhinoceros Population

high i.e. a high birth rate is required. For the maintenance of a demographically stable population the distribution of individuals in each age class is necessary.

## Life tables

The life table of male and female one horned rhinoceros in captivity in India are presented in table 11. The mortality rate ( $Q_x$ ) for males and females peak in the first year of life. Additional peaks are observed once again in the 21<sup>st</sup>, 29<sup>th</sup> and 33<sup>rd</sup> years in males and 21<sup>st</sup>, 27<sup>th</sup>, 33<sup>rd</sup>, 34<sup>th</sup>, 36<sup>th</sup> and 40<sup>th</sup> year in females. Fecundity ( $M_x$ ) in males peaks in the 10<sup>th</sup> year and in females in the 11<sup>th</sup>, 14<sup>th</sup> and 17<sup>th</sup> year of life. Special care must be taken in young calves to reduce the mortality rates in the 1<sup>st</sup> year of life. For breeding purposes attempts must be made to use the peak reproductive time in the lifespan of the captive individuals.

The projected population growth rates of the population as determined by analysis of the life table are depicted in table 11. It shows that the captive one horned rhinoceros population in Indian zoos is declining. All the indices used to measure population growth show negative trends.

**Table 12 Projected population growth rates**

	Males	Females
r	-0.0499	-0.0342
lambda	0.9514	0.9664
R <sub>0</sub>	0.368	0.602
T	20.05	14.86

**Mortality Rate [Q<sub>x</sub>]** the proportion of individuals that die during an age class. It is calculated from the number of animals that die during an age class divided by the number of animals that were alive at the beginning of the age class (i.e.-"at risk")

**P<sub>x</sub>, Age-Specific Survival** – The probability that an individual of age x survives one time period; is conditional on an individual being alive at the beginning of the time period. Alternatively, the proportion of individuals which survive from the beginning of one age class to the next.

**Fecundity Rate [M<sub>x</sub>]** The average number of same-sexed young born to animals in that age class. The fecundity rates provide information on the age of first, last, and maximum reproduction.

**I<sub>x</sub>, Age-Specific Survivorship** – The probability that a new individual (e.g., age 0) is alive at the beginning of age x. Alternatively, the proportion of individuals which survive from birth to the beginning of a specific age class.

**Mean V<sub>x</sub>, Reproductive Value** – The expected number of offspring produced this year and in future years by an animal of age x.

**Intrinsic Rate of Increase [r]** the exponential rate at which a population with a stable age distribution grows.

**Population Growth Rate (Lambda,  $\lambda$ )** -- The proportional change in population size from one year to the next. Lambda can be based on life-table calculations (the expected lambda) or from observed changes in population size from year to year. A lambda of 1.11 means a 11% per year increase; lambda of .97 means a 3% decline in size per year.

**Net Reproductive Rate [R<sub>0</sub>]** if each animal were to replace itself each generation, the net reproductive rate would be 1.00 and the population would remain the same size. A growing population has an R<sub>0</sub> greater than 1.0 and a declining population less than 1.0.

**Generation Time (T)** -- The average time elapsing from reproduction in one generation to the time the next generation reproduces.

## Population Projections

A population projection for a stable age distribution of the one horned rhinoceros in captivity in Indian zoos was generated using PM2000. It was assumed that for ensuring a genetically viable and demographically stable population an increase in the population from the current 47 specimens to 100 over the next 10 years would be required. For a stable population a steady decline is observed in figure 6 while the actual population shows an exponential increase over the next 10 years and then stabilizes at 100 individuals for the next 40 years. Details of the number of individuals required for a stable population are presented in table 13. The first row # Born – represents the number of births required each year to achieve a stable population.

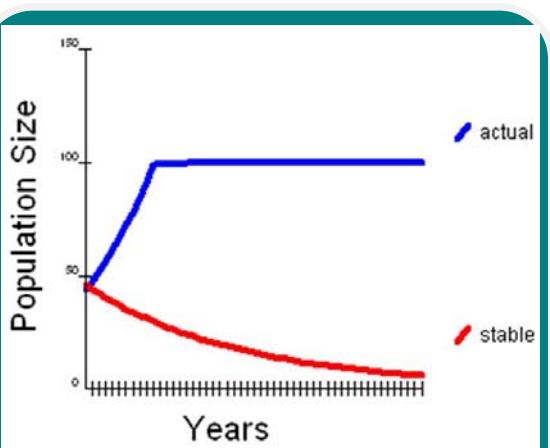

Figure 6 Population projections for the Indian captive one horned rhinoceros population

Table 13 Population projections for the captive one horned rhinoceros population for the next 50 years

# Genetic Analysis

Species with small and declining populations are faced in with the loss of genetic variability due to the limited mating choices available and the small sample of the original gene pool being represented. In captive populations of these species the problem is further exacerbated by the much reduced sample size of the original gene pool of the species. It therefore becomes imperative to genetically manage captive populations of threatened species.

The genetic summary of the captive one horned rhinoceros Indian population is presented in table 5. The table suggests that the genetic variability of the population could be much higher than that at present.

## Founder Statistics

An analysis of the founder statistics of the Indian captive one horned rhinoceros population presented in table 14 and figure 7 depict the contribution made by each specimen of wild origin to the captive population. It is inferred that a few individuals (studbook numbers – 7, 8, 26, 34, 36, 49, 62 and 65) are over represented while others are underrepresented or not represented at all. An equal representation of all founder animals could have significantly enhanced the genetic variability of the current population.

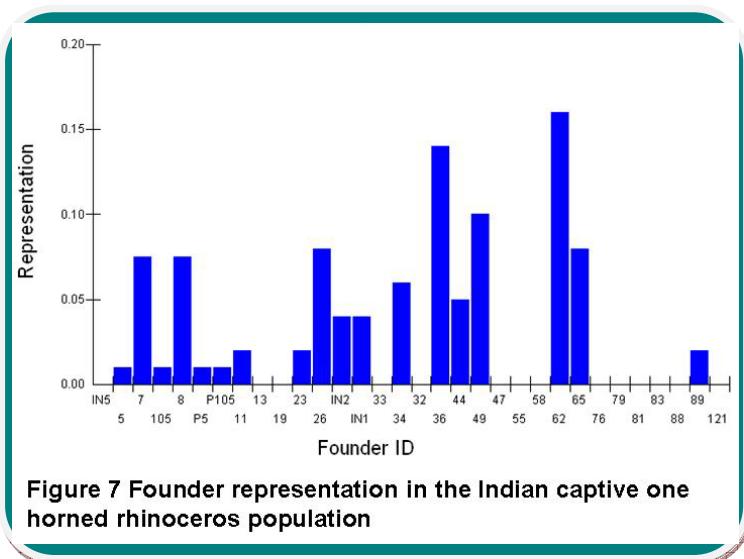

Figure 7 Founder representation in the Indian captive one horned rhinoceros population

## Individual statistics

The genetic details of the living specimens in the Indian captive one horned rhinoceros population are presented in table 15. The information contained in the table can be used to manage pairings. Specimens with low inbreeding coefficients and mean kinship values are suitable for breeding purposes than those with higher values. Similarly individuals with a large number of offspring (progeny) are less preferred over those with no offspring or a few offspring. The selection of individuals with no offspring or few offspring brings their gene pool into the population which would otherwise go unrepresented or underrepresented.

## Inbreeding Statistics

The inbreeding statistics of the Indian captive one horned rhinoceros are presented in table 16. Specimens with studbook numbers 108, 109, 117, 119, 120 and 124 have significant levels of inbreeding coefficient and they or their offspring would carry a smaller portion of the gene pool that can be represented in individual specimens. These individuals should be used with caution for breeding purposes only when absolutely necessary.

**Table 16 Inbreeding Statistics**

Studbook #	Sex	Age	Location	% Known	Inbreeding coefficient (F)

## **Conclusion**

One horned rhinoceros are mega herbivores inhabiting the riverine grasslands in the Himalayan foothills. The species earlier listed as endangered has shown recent signs of recovery and is currently listed as vulnerable in the IUCN Red List of Threatened species. The species is currently managed as part of an international effort and has several zoos holding the species outside India.

Indian zoos currently have 33 (18.15) specimens in captivity. Analysis of the captive Indian population suggests that the current population has a high level of genetic diversity but is threatened by low numbers. A target population size for Indian zoos of 100 individuals to be achieved over 10 years is suggested for maintaining a genetically viable and demographically stable population. The current population has several animals of wild origin whose genes are not represented or underrepresented in the captive population. A more equitable representation of the founder gene pool would enhance the genetic stability of the captive population.

# Glossary of Terms

## Demographic Terms

**Age Distribution** -- A two-way classification showing the numbers or percentages of individuals in various age and sex classes.

**Population Growth Rate** (Lambda,  $\lambda$ ) -- The proportional change in population size from one year to the next. Lambda can be based on life-table calculations (the expected lambda) or from observed changes in population size from year to year. A lambda of 1.11 means a 11% per year increase; lambda of .97 means a 3% decline in size per year.

**P<sub>x</sub>, Age-Specific Survival** – The probability that an individual of age  $x$  survives one time period; is conditional on an individual being alive at the beginning of the time period. Alternatively, the proportion of individuals which survive from the beginning of one age class to the next.

**Q<sub>x</sub>, Mortality** – Probability that an individual of age  $x$  dies during time period.  $Q_x = 1 - P_x$

The proportion of individuals that die during an age class. It is calculated from the number of animals that die during an age class divided by the number of animals that were alive at the beginning of the age class (i.e.-at risk).

**I<sub>x</sub>, Age-Specific Survivorship** – The probability that a new individual (e.g., age 0) is alive at the *beginning* of age  $x$ . Alternatively, the proportion of individuals which survive from birth to the beginning of a specific age class.

**M<sub>x</sub>, Fecundity** – The average number of same-sexed young born to animals in that age class. Because SPARKS is typically using relatively small sample sizes, SPARKS calculates M<sub>x</sub> as 1/2 the average number of young born to animals in that age class. This provides a somewhat less noisy estimate of M<sub>x</sub>, though it does not allow for unusual sex ratios. The fecundity rates provide information on the age of first, last, and maximum reproduction.

**V<sub>x</sub>, Reproductive Value** – The expected number of offspring produced this year and in future years by an animal of age  $x$ .

**E<sub>x</sub>, Life Expectancy** – Average years of further life for an animal in age class  $x$ .

**Risk (Q<sub>x</sub> or M<sub>x</sub>)** – The number of individuals that have lived during an age class. The number at risk is used to calculate M<sub>x</sub> and Q<sub>x</sub> by dividing the number of births and deaths that occurred during an age class by the number of animals at risk of dying and reproducing during that age class.

## Genetic Terms

**(Founder) Contribution** -- Number of copies of a founder's genome that are present in the living descendants. Each offspring contributes 0.5, each grand-offspring contributes 0.25, etc.

**Current Gene Diversity (GD)** -- The proportional gene diversity (as a proportion of the source population) is the probability that two alleles from the same locus sampled at random from the population will be identical by descent. Gene diversity is calculated from allele frequencies, and is the heterozygosity expected in progeny produced by random mating, and if the population were in Hardy-Weinberg equilibrium.

**Effective Population Size** (Inbreeding  $N_e$ ) -- The size of a randomly mating population of constant size with equal sex ratio and a Poisson distribution of family sizes that would (a) result in the same mean rate of inbreeding as that observed in the population, or (b) would result in the same rate of random change in gene frequencies (genetic drift) as observed in the population. These two definitions are identical only if the population is demographically stable (because the rate of inbreeding depends on the distribution of alleles in the parental generation, whereas the rate of gene frequency drift is measured in the current generation).

**FOKE, First Order Kin Equivalents** – The number of first-order kin (siblings or offspring) that would contain the number of copies of an individual's alleles (identical by descent) as are present in the captive-born population. Thus an offspring or sib contributes 1 to FOKE; each grand-offspring contributes 1/2 to FOKE; each cousin contributes 1/4 to FOKE.  $FOKE = 4 * N * MK$ , in which N is the number of living animals in the captive population.

**Founder** – An individual obtained from a source population (often the wild) that has no known relationship to any individuals in the derived population (except for its own descendants).

**Founder Genome Equivalents (FGE)** – The number wild-caught individuals (founders) that would produce the same amount of gene diversity as does the population under study. The gene diversity of a population is  $1 - 1 / (2 * FGE)$ .

**Founder Genome Surviving** – The sum of allelic retentions of the individual founders (i.e., the product of the mean allelic retention and the number of founders).

**GU, Genome Uniqueness** – Probability that an allele sampled at random from an individual is not present, identical by descent, in any other living individual in the population. GU-all is the genome uniqueness relative to the entire population. GU-Desc is the genome uniqueness relative to the living non-founder, descendants.

**Inbreeding Coefficient (F)** -- Probability that the two alleles at a genetic locus are identical by descent from an ancestor common to both parents. The mean inbreeding coefficient of a population will be the proportional decrease in observed heterozygosity relative to the expected heterozygosity of the founder population.

**KV, Kinship Value** – The weighted mean kinship of an animal, with the weights being the reproductive values of each of the kin. The mean kinship value of a population predicts the loss of gene diversity expected in the subsequent generation if all animals were to mate randomly and all were to produce the numbers of offspring expected for animals of their age.

**Mean Generation Time (T)** -- The average time elapsing from reproduction in one generation to the time the next generation reproduces. Also, the average age at which a female (or male) produces offspring. It is not the age of first reproduction. Males and females often have different generation times.

**Mean Kinship (MK)** -- The mean kinship coefficient between an animal and all animals (including itself) in the living, captive-born population. The mean kinship of a population is equal to the proportional loss of gene diversity of the descendant (captive-born) population relative to the founders and is also the mean inbreeding coefficient of progeny produced by random mating. Mean kinship is also the reciprocal of two times the founder genome equivalents:  $MK = 1 / (2 * FGE)$ .  $MK = 1 - GD$ .

**Percent Known** -- Percent of an animal's genome that is traceable to known Founders. Thus, if an animal has an UNK sire, the % Known = 50. If it has an UNK grandparent, % Known = 75.

**Prob Lost** – Probability that a random allele from the individual will be lost from the population in the next generation, because neither this individual nor any of its relatives pass on the allele to an offspring. Assumes that each individual will produce a number of future offspring equal to its reproductive value,  $Vx$ .

**(Founder) Representation** – Proportion of the genes in the descendant population that derives from that founder. I.e., proportional Founder Contribution.

**Allele Retention** – The probability that a gene present in a founder individual exists in the living, descendant population.
