In his 1891 report Cope assigned certain remains of Aceratheres from the Cypress hills to this species. They consist of parts of two lett mandibular rami, and are referred to as specimens Nos. 1 and 2. The first specimen is a section of a left ramus holding the roots of the last two molars, and extending back beneath the base of the coronoid; the fragment is 87 mm. long. The second is part of the anterior half of another left ramus, with premolars 3 and 4 preserved, the roots of premolar 2, and the inner end of the alveolus of a procumbent canine. A figure was given (pl. IV, fig. 2, pt. I of this volume) of this second specimen viewed from above.

A symphysis of a mandible, also from the Cypress hills, described and figured by Cope in 1891, under the name Compus pumilus, in the same publication as the above, is regarded by Osborn (op. cit. 1898) as properly referable to A. mite. The second of the two specimens on which C pumilus was founded (pt. I, this volume, pl. IV, fig. 4) has been shown by Professor Osborn (op. cit. 1898) to be part of the lower jaw of Hyracodon nebrascensis.

In the type ramus from Colorado, described by Cope in 1874, the space occupied by the first three lower premolars (2, 3 and 4) is 80 mm. as given in the original description. A similar measurement, taken from the "type lower jaw" (and therefore presumably from the same specimen), is stated by Osborn (op. cit. p. 139) to be 55 mm. In specimen 2 from the Cypress hills (A. mite) the three premolars together measure in length 58 mm, and in the symphysial specimen (C. pumilus) a like measurement gives 43 mm. In one only of the three Cypress Hills specimens referred to A. mite, are premolar crowns preserved, and in the type ramus the crowns of the three premolars are imperfect.

A very perfect lower jaw from the Protoceras beds of South Dakota is referred doubtfully by Osborn (op. cit. p. 139) to this species. The premotar series in this last specimen occupies a space of 47 mm.

An upper left third molar tooth, obtained by T. C. Weston at the Cypress Hills locality in 1884, is probably referable '2 this species. Its dimensions are :—antero-posterior diameter, 25 mm., transverse diameter 28 mm.

A much larger tooth, plate 1V, fig. 6, an upper right posterior molar of the 1904 collection, compares favourably in size and general proportions with the third molar of Leptacera therium trigonodos, Osb. and Wort. Its diameters measure, antero-posterior, 31 mm., transverse 37 mm.

ACERATHERIUM OCCIDENTALE (Leidy).

I'late IV, fig. 7.

Rhinoceros occidentalis, Leidy, 1851. Proc. Acad. Nat. Sci. Phila., vol. V. p. 276.

This species is recorded by Cope (this volume, pt. I) from the Oligocene of the Cypres hills. A number of lower jaw tragments, belonging both to the collection of 1904 and to the earlier collections, apparently represent species distinct from A. mite and A. occidentale, but they are too imperfect for determination.

An inferior left posterior molar (collection of 1904) evidently belongs to this species. In it the basal clingulum is developed in front and behind but not on the exterior and interior surfaces. Diameters—antero-posterior 32 mm., transverse 21 mm.

ACERATHERIUM EXIGUUM, Sp. nov.

Plate V, figs. 8, 4 and 5.

A mandibular symphysis, collected by the writer in Bone coulée, Cypress hills, in 1904 has entirely different proportions to the symphysis (Canopus pumilus, Cope) from the same locality, already referred to A. mite. This specimen consists of almost exactly the same parts of the jaw preserved in the symphysis of C. pumilus, viz., the anterior end of the left ramus and a short length of the right careus united with it so as to show the extent and form of the symphysis. No crowns of teeth are preserved, but in the left ramus the roots of premolars and 3 remain. The alveoli for the canine and for one incisor in each ramus are preserved, as well as the alveolus for premolar 2 in the right ramus, and the anterior half of the alveolus for premolar 3 in the left.

Comparing it with the symphysial specimen of *C. pumilus*, the following differences are apparent:—a narrower and longer symphysis, having increased depth behind; a more rapid despening of the ramus from in front backward, with a corresponding increase in transverse thickness; a greater space occupied by the first two premolars; and very much larger canines as indicated by their alveoli. The greater depth of the ramus beneath the first two premolars is very noticeable.

In this specimen, belonging to the 1904 collection, the diastema is of about the same length as that of C. pumilus. The alveoli for the canines are 8 mm. apart in front, and close together at a lower level are those for two incisors, one on each side of the median line. Premolar 2 was a tooth of fair size with two well separated roots.

A small species of Acerathere, slightly exceeding A. mite (pumilum) in size, is here represented, to which the name exignum is given. The jaw is more robust than in A. pumilum, its main characteristics being the contracted and lengthened symphysis and the enlarged canines.

V, figs. 1 and 2, pl. VI, figs. 1, 2, 2n, pl. VII, figs. 1, 1a, 1b, pl. VIII, figs. 1, 2, 3 and figures of leg and foot bones.
- Titanotherium angustigenis, Osborn, 1896. The Cranial Evolution of Titanot'erium, Bulletin Amer. Mus. Nat. Hist., vol. VIII. p. 184.
- Megacerops angustigenis, Osborn, 1902. The Four Phyla of Oligocene Titanotheres, idem, vol. XVI, p. 99.

This species apparently approaches closest to M. coloradensis, Leidy, founded on coössified nasals with horns attached. In the Cypress Hills species the horns are much farther apart, with a flatter surface separating them. Also the nasals, besides being shorter, expand laterally in front instead of narrowing rapidly as in M. coloradensis.

Cope, in the American Naturalist, 1889, p. 153, made this species the type of Haplacodon, a generic term discarded by him in his later writings.

The species, of which the full description with figures is given in part I of this volume, is based on two maxillary bones from the same individual, a separate left ramus, and the symphysial part of another jaw. With these were associated, as probably belonging to the same species, an imperfect cranium, and certain separate leg and foot bones. One of the maxillary bones, the left ramus, and the nasal bones with horns and part of the frontal, were figured in plates V, VI, VII and VIII. In plate VI, figure I, a view from above was given of the coössified masals shown in side and front view in plate VIII, and belonging to the cranium mentioned above. Through an error in the explanation of plate VI, these nasals (fig. 1) were ascribed to Menodus? americanus, Leidy, instead of to Menodus angustigenis. This error has been repeated in Professor II. F. Osborn's paper "The Cranial Evolution of Titanotherium," Bull. Amer. Mus. of Nat. Hist., 1896, foot note p. 175.
