INTRODUCTION.

This report is a revision of the working-plan for the Jalpaiguri Forest Division, sanctioned in the Government of Bengal's letter No. 4320, dated 5th December 1899, for ten years, with effect from the Forest year 1896-97, which consequently expires at the end of the Forest year 1905-06.

In the ordinary course the provisions of a revised plan would come into effect from the Forest year 1906-07, but doubts having arisen as to the suitability of the prescriptions of the plan under revision, the forests were visited by the Inspector-General of Forests, and in a note, dated 7th February, 1904, he advised that an alteration in treatment should be introduced without delay. In anticipation of orders, Improvement fellings were substituted for Coppice with Standards in the sâl bearing areas in the season of 1903-04, though the area worked over remained unchanged. In the following working season, 1904-05, fuller effect was given to the Inspector-General of Forests' recommendations. These alterations in treatment were sanctioned by the Local Government in their letter No. 999, dated the 28th May 1904. Some delay has occurred in the preparation of the revised plan owing to the writer having only assumed charge of the Division in November 1903, and being required to make a personal inspection of all portions of the area dealt with and to collect the necessary information in order to draw up the revised plan. The preliminary report on the working-plan was approved by the Inspector-General of Forests in his letter No. 5 W. P., dated the 26th July 1905, and the Government of Bengal have sanctioned the proposals therein being given effect to at once in their letter, No. 2950 T.R., dated the 11th September 1905. The present plan should be read in conjunction with the original plan as

The present plan should be read in conjunction with the original plan as it has not been considered necessary to reproduce all the information given therein.

No special outlay has been incurred in the preparation of this plan, the work having been done by the Divisional Forest Officer alone in addition to his own duties.

> F. TRAFFORD, Deputy Conservator of Forests, Jalpaiguri Division.

COLLEGE OF A AGRICULTURE

ISION OF

SUMMARY OF FACTS ON WHICH THE PROPOSALS ARE BASED.

CHAPTER I. DESCRIPTION OF THE TRACT DEALT WITH.

Section 1. General description.

I. There is hardly anything to add to the description given in the original plan. Severe frost was observed in February 1904. The extension of cultivation of all crops has changed the appearance of the country outside the forests and reduced the area available for grazing.

CHAPTER II. COMPOSITION AND CONDITION OF THE FORESTS.

Section 1. Distribution and area.

2. The area of the Forests is now 113,606 acres=177 square miles. Since 1896, 3,259 acres have been excluded from the forests as follows:—

2609 acres, comprising the whole of the Tista Forest, have been disforested under Government of Bengal Notification, No. 2607 T. R., dated 28th August 1905.

502 acres, comprising the area taken up for Railway construction are now under the control of the Bengal Duars Railway Company.

148 acres, erroneously considered to be within the Reserved Forests, was found to have been included in the grant leased out to the Gairkhata Tea Company and was restored to this company in 1902.

Section 2. State of boundaries.

3. The only other changes of boundary not caused by the above change of area have been due to alterations in the courses of certain rivers previously gazetted as natural boundaries, notably the Dharla, Jaldáka and Dainah rivers. These rivers, by depositing boulders and stones in their own beds, raise the level of these beds until they overtop the surrounding country when the river changes its course; as the old beds soon get covered up with grass and tree growth, their courses are apt to become obliterated in a few years. In one instance a change of river bed has obliterated a demarcated boundary but it will not be so difficult to relay this at any future time as the artificial boundary runs straight for a considerable distance.

there is involved as a final state and analy should state a final should be a state of the second state of the

the Vouter most synth days trans been removed.

Section 3. Legal position. 4. No alterations have to be recorded.

....

il

Section 4. Rights. 5. No rights exist. 6. The previous working-plan goes into this in great detail giving eight different types. For the purposes of this plan it will be sufficient to distinguish only four types which merge into one another and are found in many places inextricably combined. These are (a) Sâl, (b) Mixed (dry) (c) Evergreen (d) Savannah. The main changes which have taken place have been the spreading of sâl, mixed and evergreen forests into the savannah and the partial retrogression of the sâl forest. This has changed the appearance of the forests considerably in certain parts.

7. Besides this, owing to the past method of working, some 3,594 acres have been converted from High Sâl forests to Coppice with Standards, (see Appendix IV.) Of this area 896 acres was worked over before 1896-97. Had the prescriptions of the plan been fully worked up to, an area of 5,439 acres of sâl forest would have now become Coppice with Standards; owing to want of demand for firewood, however, an area of 1,845 acres escaped being exploited.

8. The condition of the area worked over under Coppice with Standards varies according to the age of the coupe. In the first two or three years after felling, the coppice shoots hold their own fairly well, but by the 4th year the dense mass of creepers which make their appearance as soon as light is let into the forest overtop and smother all coppice shoots. Coppice shoots of sâl get bent by the weight of the creepers above them and appear to lose their vitality. In the 6th year coppice shoots and seedlings of other species, such as *malota*, have overtopped the sâl coppice shoots and seedlings which, except in favourable localities, appear as half dead, suppressed saplings in the 10th year, and by the 12th year have almost disappeared, the forest having become a dense thicket of creepers and poles, 18" to 24" in girth and some 30' high, with a few standards of sâl scattered here and there. The first coppice felling took place in 1892-93.

9. This tendency is shown in a marked degree by a recounting in conversion of såi into evergreen forest. the Dumchi sål area (244 acres) made after an interval of 10 years had elapsed after the first counting.

TT C	erti dere schel ander Verschop a ble summer	Diameter classes.					
Year of counting.	Seedlings under 3″ diameter.	3**•6"	6''-9"	9"-12"	12"-15"	15"-18"	
1894-95	Not recorded	2,212	2,636	2,832	2,732	1,870	
1904-05	Very scarce	1,200	1,663	2,523	2,784	2,264	
Increase			•••	•••	52	394	
Decrease	•••	1,012	973	309			

The following shows the result :--

This shows that, though there was ample room for an increased production of sâl, large number of seedlings and small poles have disappeared, and there must have been very few replacements. This area has been closed to the felling of sâl, and only dry trees have been removed.

Appendix II shows the results of measurements taken in sample 10. plots. They confirm the impressions already prevalent Rate of growth given by sample plot measurement. that the growth of sal is more rapid the further east it grows in the Jalpaiguri Division, the growth in Muraghát being more rapid than that in Tondu and a long away ahead of the growth in Apalchand Forest. The difference in growth between trees in untouched forest and the standards in coppiced coupes is remarkable. This difference is not so great as one would be led to expect from the appearance of the position of the trees in both cases, particularly when it is taken into consideration that the standards selected are the best grown and healthiest trees, whereas no discrimination was made in the case of the trees in the untouched forest over half of which would have been removed. Had only trees which would have been reserved as standards been measured in the latter case, it would have been interesting to note the result.

11. The area statement is given in Appendix I.

Section 6. Injuries to which the crop is liable.

12. Fires. A list of fires which occurred during the last eight years is given in Appendix VII. Creepers. The work done in cutting climbers is given in Appendix III.

Creepers. The work done in cutting climbers is given in Appendix III. Frost. Frost injured numbers of *malota* trees where they were exposed in grass areas during February 1905.

Hail. A hail storm in April 1900 defoliated all sâl trees in North Tondu forest.

Storm. A cyclonic storm in April 1904 uprooted some 3,000 sål trees a large proportion being over 6 feet in girth.

Insects. Defoliators have constantly attacked sâl. The year 1899 being a particularly bad one; after the cyclone in 1904 a number of standing sâl trees were killed by beetles which attacked them, and many of the windfalls were found to be full of larvæ.

CHAPTER III. SYSTEM OF MANAGEMENT.

Section 1. Past and present system of management.

13. The past system of management is clearly explained in the working-plan now under revision and the present system of management is that laid down in Part II. below.

Section 2. Special works of improvement undertaken.

14. These are also prescribed in the plan under revision. Appendix III. shows the work done in creeper cutting.

Section 3. Past revenue and expenditure.

Section 2. Lines of export.

E CONTRACTOR

17. The working-plan under revision, (pages 26, 27,) goes fully into the lines of export which, with the exception of the railway which has extended eastwards from Mál to Madárihát, have not altered appreciably.

18. The Tista and the Dudua are the only rivers utilized for floating purposes. The former is practically open the whole cold weather but the latter, passing via the Jaldáka and Dhurla rivers into the Brahmaputra, is only open for a month or two after the end of the rains. The other rivers have too rapid a current to enable boats to be brought up stream without difficulty and the same objection applies to the first-named rivers during the rainy season.

19. Timber is mostly exported by rail owing to the convenience of rapid transit, but the rates are so high that export by cart to markets south of the district still obtains. Rámshai, Bárodighi and Látaguri on the Bengal Duars Railway are the main stations for the export of timber from the Tondu forest, and Binnaguri station would be the natural outlet for timber from the Muraghat forest, were it not that the rate on the northern section of the railway, that is 0.8 of a pie per maund, per mile, is too high to enable purchasers to profitably remove timber over the long length of line, viz., 44 miles, between Lataguri and Binnaguri, though the distance by road is only 24 miles.

The following figures show the export of timber from the District by rail over the Bengal Duárs Railway in the past five years:-

Years.	interniting the state	the of the other	Tons.	· · · · · · · · ·

11 11 127	fierds to appro	11.5.1.5	m . T zin	debiled in Alle

Section 3. Markets.

one several mon

2. Néarly every station on the Eastern Bengal State Railway is the nucleus of a market for timber, the most important being Rangpur and Nattore. Mandalghát is the chief market on the Tista river, and Mathabhanga, where the Dudua meets the Jaldáka, is a market from which timber is subsequently carried by large boats to Eastern Bengal. Tea gardens, of which thirty-three now take fuel from the forests, are almost the only customers for firewood. 2,170,282 cubic feet of firewood were removed during 1904-05.

Section 4. Mode of extraction and its cost.

21. Timber is brought to the lines of export by cart at a rate of from two annas to three annas per cubic foot up to a distance of eight miles, according to the size of the logs and the distance they have to be carried. For small logs and scantlings the rate is -/2/- a cubic foot, and for metre gauge sleepers, which are easy to load and carry, the rate is two annas each up to the same distance, which represents a day's carting.

22. Firewood costs about Rs. 5/- a 100 maunds to cut, and from Rs. 5/- to Rs. 15/- to cart according to the lead and condition of the road. It costs from Rs. 18/- to Rs. 27/- a hundred maunds, including royalty, to land wood fuel at the different tea estates, but coal is now used to a great extent, the railway having now reduced the rates so that it can be delivered at railway stations from eight to ten annas per maund.

Section 5. Net value of each class of produce.

23. The net value of each class of produce depends on the position of the forest with reference to the lines of exports and market.

Sål timber from 4 to 7 annas per cubic foot. Other ,, from 9 pics to 3 annas per ,, Sål poles from 8 annas to 8 rupees each. Other ,, from 1 anna to 8 annas ,, Firewood 1/4/- per 100 cubic feet. Grazing from 4 annas to 6 annas per head per month.

CHAPTER V. MISCELLANEOUS FACTS.

Section 1. The forest staff.

24. The following shows the forest staff at present on duty in the three Ranges.

Ran	nge.		Number.		Pay.
Apalchand	•••	{	1 1 2 2	Ranger Forest Guard Do. Do.	50 12 8 7
Upper Tondu		{	1 3	Deputy Ranger Forest Guards	35 8
Lower Toudu .	•••	{	1 1 1 3 3	Ranger Deputy Ranger Forest Guard Do. Do.	80 30 10 8 7
Muraghát .		{	1 1 2 2 3	Ranger Forester Forest Guards Do. Do.	60 25 10 8 7

The staff is sufficient in point of numbers except during the cold weather, when it is strengthened by the addition of temporary establishment consisting of overseers, special chowkidars and fire patrols. After the working season as much leave as possible is granted in turn to the permanent subordinates to enable them to recruit outside the malarious influences of the forests.

25. The pay of Forest Guards is, however, extremely low, compared with the prevailing rates for labour in the district and is a direct incentive to blackmailing and dishonesty. Frequent resignations amongst this class of subordinates tend to add to the difficulty of protection and improvement of the forest. ID SIZE OF THE IGAS IN

Section 2. Labour supply.

The greater part of the labour supply in the forests comes 26. from outside the district and is consequently unreliable; Nooniah coolies from Behar do road work and Nepalis undertake creeper cutting, line clearing etc. The rates work out to about one anna per hour's work for daily labour, creeper cutting is done at -/2/- an acre, earthwork 3/- to Rs. 5/-per 1000 cubic feet and line clearing at Re. 1/- per foot wide (cleared) per mile of length. Settlers have been permitted to settle down in the forest and cultivate; they supply labour at -/4/- per day and are invaluable for fire protection. Aid value of each class of produce,

the other and values of moduline depends on the position

of the mean with rationize to the line, of exportantial much t.

FUTURE MANAGEMENT DISCUSSED AND PRESCRIBED.

CHAPTER I. BASIS OF PROPOSALS.

Section I. Working-Circles.

27. It is necessary to make a broad distinction between :----

 (a) Sâl producing areas, and
 (b) Mixed forest containing little or no sâl
 though this distinction cannot be absolute. The sâl producing areas can be conveniently divided into 3 Working-Circles, corresponding with the three ranges which contain sâl, and these are split up into felling series as shown in the following table:----

		the second se					
Working-Circle.	Felling Series.	Block.	Sâl forest.	Mixed forest.	Total stocked area.	Total area.	Remarks.

Sal Forest.

Norr .- These Working-Circles will hereafter be referred to as the Sâl Working-Circles.

28. (b) Mixed Forest.

The Mixed Forests have been divided into two Working-Circles corresponding with the Ranges in which they occur. Owing to the disforestment of the Tista Block, there is not sufficient Mixed Forest in a compact area, in the Apalchand Range, to form a separate Working-Circle. The following table shows the constitution of Working-Circles and felling series :-

Nore-These Working-Circles will hereafter be referred to as the Mixed Working-Circles.

Section 2. Compartments; justification of the sub-division adopted.

29 No change is proposed from the sub-division adopted in the plan under revision.

Section 3. Analysis of the crop.

30 The working plan map prepared for the plan under revision has been compared, with the crop on the ground. In some places, progress in natural afforestation has been slow, but in others it is fairly clear that considerable changes have taken place. In the Apalchand Range, areas in the Udlabári, Phuljhora, Chel river and Apalchand Blocks, shown as savannah in the old stock maps, now contain mixed forest, whercas in Hanskháli and Churabhija there is no marked alteration. These types not only merge into one another but are constantly changing, and a stock map is constantly getting out of date. An attempt has been made to rectify the areas given in the old stock map to a slight extent. No sâl, for instance, was shown as existing in Indong compartment 2; whereas there are at least 100 acres of sâl in this block in the north-east corner alone, not to speak of small patches in the interior. There is also more than 6C acres of grass and 70 acres of unproductive land in Dumchi. For purposes of working, the Dainah Forest has been estimated to contain 7,700 acres and the Jaldáka Forest 1,060 acres of mixed *khair* and *sissu* forest, capable of being worked over for firewood, the balance being river bed, savannahs and grassy churs covered with *khair and sissu* seedlings.

CHAPTER II. METHOD OF TREATMENT.

Section 1. Object sought to be attained.

31 Sâl Working-Circles. The object aimed at is to produce as much sâl timber of large size and good quality as possible, and it is decided to utilise for fuel and other purposes trees of inferior kinds which can be eut out so as to benefit the sâl.

32. Mixed Working-Circles. The object is to obtain a sustained yield of firewood and produce as large a supply as possible of trees which yield timber for box planking and other purposes.

Section 2. Method of treatment adopted.

33. Sâl Working-Circles. As the number of mature sâl trees is comparatively small, and as trees of inferior species are numerous and, in many places tend to get the upper hand, Improvement fellings are prescribed. In the 8,320 acres of mixed forest included in these Working-Circles the Improvement felling will closely resemble a Coppice with Standards felling

34. Mixed-Working Circles. Coppice with Standard fellings are prescribed, as this is the only treatment likely to secure the objects aimed at.

Section 3. The exploitable age.

35. Sål Working-Circles. As in neighbouring forests the minimum exploitable diameter for sål may be assumed to be 2'; judging from the rate of growth indicated in Appendix II a sål tree of this size should be 75 years old.

36. Mixed Working-Circles. From observations made on the oldest coupes, it is fairly evident that a fair amount of fuel in good sized billets could be obtained from coppice 16 years old. To allow a sufficient margin and to give a better class of fuel, 20 years has been adopted as the exploitable age for coppice. As regards the standards, which will merely consist of different kinds of superior species, no age can be fixed upon, but all trees which have reached a girth of seven feet will be considered ripe for felling.

CHAPTER III. THE FELLINGS.

Section 1. The general working schemes and calculation of the possibility.

Timber. Sal Working-Circle-From estimates based on mark-37. ings made by the writer in the Sealduba block, Apalchand forest and Látaguri block, Lower Tondu forest, it is anticipated that the yield in timber will amount to about 55 cubic feet of sal per acre in the former and 40 cubic feet in the latter. The latter block has, however, suffered in the past from fires so that the trees which have been removed are frequently short and stunted.

38. Firewood. The quantity of firewood available varies so much that it is difficult to make an estimate, but the yield may safely be taken at 500 cubic feet per acre where there is sufficient demand to warrant its extraction.

39. Mixed Working-Circles-It is not anticipated that the yield of timber will be appreciable. The outturn of fuel varies according to the character of the crop. Taking the figures for 1904-05, the densely stocked Sipchu block yielded 1,400 cubic feet per acre, whereas, in the thinly stocked Pangjhora block, the firewood obtained worked out to only 300 cubic feet per acre. The average yield of all coupes worked under Coppice with Standards amounted to 700 cubic feet per acre.

Section 2. Period for which fellings are prescribed.

40. The most important fellings are the Improvement fellings which will take 15 years to traverse the area under treatment. Consequently fellings in all Working-Circles are prescribed for 15 years.

Section 3. Areas to be felled annually or periodically: order of their allotment.

41. In each of the Sal Working-Circles the average yearly coupe will be 15th of the productive area of the Working-Circle, i.e., of the areastocked with sal and mixed forest, except in the case of Series IL of Apalchand and the whole of the Lower Tondu Working-Circle where the annual coupe will be about $\frac{1}{15}$ th of the sal area. In the Mixed Working-Circles $\frac{1}{20}$ th of 1976 of the productive area will be worked over annually. The whole area of every Working-Circle will be open to the extraction of dry timber at the discretion of the divisional forest officer.

42. The order of the allotment of the fellings is given in the tabular statement at the end of this chapter and for Improvement fellings, the position of the areas to be worked over is clearly shown in the map annexed to this report.

Section 4. Nature and mode of executing the fellings.

43. Sål Working-Circles:-In these the exploitation of sål will include the removal of :---

(a) all sâl trees over 2 feet in diameter,

(f) it's blacket of at a fair account of tool, in grad sized about fixing explanetic scare thin of buildows sufficients a better came or that, 20 years fair fixed block of a scare or the scare of the first first block of a star.

give in the delider of infinite site elong side and a

(b) all sal trees which show signs of deterioration being dead, hollow, crooked, or top-broken and ---

the store barit of an an entrate strates at some in the first work of the and in a second second and a second second

In addition to this, thinnings will be made amongst dense sål poles, some of which must be suppressed in the course of the next fifteen years. These latter must be marked with great eare. The exploitation of other kinds of trees will consist in the removal of all trees over 18" girth where there is a demand for them, but where there is no such demand, only those trees which dominate advance growth of sål should be cut. As the cutting of the inferior species of trees eannot benefit the advance growth of sål unless it is followed by the successive weedings and cleanings prescribed in para 48 it is necessary to prescribe that the cutting of such trees in sål areas shall not continue unless the weedings, are up to date. It may be noted that it is anticipated that there will be a large demand for inferior trees for fuel in the Muraghåt Sál Working-Circle and in Series I of the Apalchand Sål Working-Circle, but there will probably be little demand for fuel in the Lower 'fondu Sål Working-Circle and Series II of the Apalchand Sål Working-Circle.

The Improvement fellings will practically be Coppiee fellings in those areas devoid of sâl and containing only evergreen or mixed species of trees.

44. Mixed Working-Circle.—Standards should be selected before coppice felling starts. All promising trees of the following species of less than 7 feet in girth being marked for reservation, i. e., sal, sissu, chámp, tun, goguldhup, mallagiri, kainjal, simal and kadam.

Where the forest consists of almost pure *khair*, not less than forty poles to the acre should be reserved. Where there is any considerable amount of sâl, the fellings should, as far as possible, resemble the Improvement fellings prescribed in the sât areas. It will probably be unnecessary to work over the sâl forest included in these Working-Circles. Should it, however, be found necessary to do so, it must be worked over under the method of Improvement fellings laid down for Sâl Working-Circles. It is not antleipated that any exploitation will take place in the Muraghát mixed Working-Circle owing to want of demand at present, as tea gardens in the vicinity have sufficient firewood in their grants to last them another ten years.

Section 5. Forecast of the condition of the crop at the conclusion of the fellings.

45. Sâl Working-Circles. Where trees of inferior species are saleable, there should be a considerable increase in the stand of sâl timber. Trees of all ages will be well represented, and there should be a good stock of sâl saplings to form an extension of sâl forest wherever the soil is suitable for the growth of sâl. Trees of miscellaneous species will all be of comparatively small dimensions. Where inferior trees eannot be disposed of, improvements will probably be less marked.

46. Mixed Working-Circles. This will contain forest of coppice shoots and seedlings, chiefly of miscellaneous species, but with a higher proportion of sâl, *chámp* and other more valuable species. The coppiced forest will range in age from 1 to 20 years and each of the age classes will occupy approximately equal areas unless there are fluctuations in the demand. There will also be patches of high forest of sâl, particularly in the Lower Tondu, as the demand will not, in these series, reach the supply available. The sâl area in Dumchi will also be held in reserve. It is possible that the remote portions of the forest in the Upper Tondu series may not be completely worked over owing to the increasing use of coal of which the price already low may fall still lower. Section 6.

Muraghat Mixed Forest Working-Circle.

CHAPTER IV. MISCELLANEOUS REGULATIONS.

Section 1. Thinnings, cleanings & weedings See Appendix VIII (c):

48. Sal Working-Circles: After a felling has been made it will be necessary to weed the parts of the coupe which are not already well stocked with sal or do not contain merely mixed or evergreen forests in which there is no sign of sal reproduction. This weeding or clearing will be annually repeated until the sâl is established. On the areas to be weeded there is usually a good or fair supply of small sal seedlings, and past experience makes it certain that large numbers of additional sal seed-lings will germinate in the year following the fellings. Though the cover of the numerous reserved sal trees will restrain the growth of inferior trees and plants to some extent, the latter would, nothing being done to help the sal seedlings, rapidly get the better of the latter which will either die or form straggling bushes by the end of the felling rotation. Sal seedlings hold their own fairly well during the year following the improvement felling. In the second year, however, the coppice of inferior species, small creepers, malota seedlings etc., get the better of them and though they do not necessarily suffer greatly up to the end of the second year, they are by that time covered over, pinned down by small, creepers and generally doomed, failing assistance. Nothing being done, they are, by the end of the third year, hopelessly out of the struggle and from that time onwards the survivors only form an undergrowth. A number generally live on till the tenth or twelfth year, and may possibly be capable of surviving much longer, but such survivors make no headway. The question as to the frequency of these weedings and clearings can best be determined by experiment, but there is no doubt

.

that they should be begun not more than two years after the improvement felling and should be continued uill the fifth year, (inclusive) after that felling. It will probably be found to cost less if a preliminary thinning and weeding, consisting of a cutting back of the neighbouring coppice shoots and rooting up of small seedlings of less valuable species, is made in the first year after felling. It is accordingly prescribed that after an improvement felling, each coupe so dealt with, should be weeded and cleaned every year for five years in accordance with the table given in Appendix. VIII. C. These cleanings will hardly be necessary or possible in those coupes where there is no demand for trees of inferior species. The results of these weedings should be considered after the fifth year, i. e., in 1909-16 when a supplementary table of weedings or cleanings should, if necessary, be prescribed.

Section 2. Creeper cutting. See Appendix VIII (d).

49. Sâl WorkingC-ircles. The large trees in the Muraghát Working-Circle, Series I of the Apalchand Working-Circle and a great part of the Lower Tondu Working-Circle, have been cleared of climbers, and it will be sufficient if, in these areas, climbers are cut in the year preceding the felling and this may well be done at the time of marking the coupe. In the Chengmári (Apalchand,) Gosaihát and that part of the Tondu forest in which climbers have been untouched, they will be cut as soon as possible. The whole of this work is prescribed for the first year and any balance not cut must be worked over as early as possible in succeeding years.

50. Mixed Working-Circles—The mere cutting of creepers in coupes recently felled is hopeless, and though it has been tried over and over again in the coppice coupes, owing to the vigour of the regrowth, no trace of it is apparent. The killing out of creepers cannot be accomplished until there is a fairly complete canopy overhead. A systematic attempt to eliminate creepers altogether should, therefore, be deferred till the tenth year after the coupe has been worked out. Where, as in the Chapramári coupe, there is a fair amount of sâl reproduction, though there are few mature sâl trees, measures should be taken to keep these cleaned annually.

Section 3. Grazing and other rights.

51. Grazing will be allowed in all areas where it is at present permitted The chief grazing grounds are the Dainah and Jaldáka forests, and the value of the grazing is probably far greater than that of the wood produced on these areas. There are no grazing or other rights requiring control.

Cection 4. Sowings, planting, or other works special to each Circle.

52. The sowing of *lampatia* and *tun* in the annual coupe in the Sipchu series will be continued and, if labour can be obtained, similar sowings may be carried out in other coupes of the Tondu Mixed Forest Working-Circle. There are no very suitable sites for forest villages in this Working-Circle, even if it was not infested by wild elephants, and local labour is very difficult to obtain during the rainy season. Experiments should be made to get over the difficulty of the cleared soil in beds, prepared for sowing, being washed down by heavy rain, before the seedlings become properly established, without throwing too heavy a shade over them.

inter of an example doministration on reaching that any one to the value of the val

of coldination is sumpled with all exact a fina will be cut and only down down by electronic to a second the growthilty of the growthing to the second the second to a second by plotting to lines prove a second to

53. The planting of bamboos along roads and boundaries should be continued and the creation of natural fire lines by ploughing up savannah lands and sowing *malota* and other quick growing species should be carried out in all Working-Circles, where grass lands form a menace to adjoining sal reproduction owing to their liability to be burnt.

54. The sowing in lines of sal in pure malota pole forest on old village sites in Muraghát may also be carried out as it is not an expensive operation. Care should be taken that abandoned fields in Garo villages are sown with malota before grass reappears on them.

An experiment in the way of sowing sál in lines in 10 year old coupes may also be tried.

Section 5. Improvements common to the whole area.

55. Roads. The existing roads where they pass through swampy ground should be embanked and where necessary Ranigunj pipe culverts should be inserted to allow of the passage of water where the flow is not too great. The object is to make such roads passable after winter or spring showers when there is sufficient water to make carting difficult and troublesome, but not impossible. To keep such roads open throughout the rains would mean expensive bridging and, as carts are difficult to obtain, at this season, it would serve no useful object. In clearing lines for paths and firelines, large sized shady trees should be preserved and the upper canopy of the forest left as dense as possible as the grass and undergrowth fill up a road every rains when the road is much exposed to the light. Regard should be had to this when a road happens to traverse a coupe open for felling. The construction of heavy strong low bridges over which elephants could pass and which would be under water in the rainy season should be undertaken, as ordinary high light wooden bridges last a very short time in the evergreen forest which lines the streams. The cutting of more paths for inspection and fire protection purposes is required. The detailed prescriptions will be found in appendix VIII (a).

56. Buildings. Another rest house is required in the Apalchand Range near Udlabári and more rest houses for Rangers and Foresters are required. Mat walls are objectionable in many ways and should be done away with; roofs which will keep out the rain and heat without being liable to danger from fire should be introduced. When a bungalow is situated on high ground, where piles are unnecessary, the latter should be avoided as they may necessitate the pulling down and reconstruction of the whole bungalow when they decay Buildings suggested arc entered in Appendix VIII b.

Protection from fire.

57. Sál Working-Circles. There are still large savannahs in nearly all Working-Circles, and it is desirable they should be filled in with forest as early as possible, and to this end they should be protected in whole or in part. Savannahs will only be burnt for definite reasons given below From the point of view of fire protection the fire protected area may be divided into three classes:—

(a) Savannahs of almost pure grass;

(b) Edges of savannah where the forest is encroaching on to the grass and forest with a grassy undergrowth, and--

(c) Dense forest with perhaps a few tussocks of grass but with ordinarily no more combustible material than dry leaves.

It may be laid down that fire does no considerable damage in (a) and that (b) is the area which should be preserved with especial care. Savannahs will only be burnt in part where they adjoin (1) boundaries (2) railway lines (3) public roads and (4) forest settlements when an extension of cultivation is wanted. In all cases a line will be cut and beaten down by elephants, so as to avoid the possibility of the area (b) being burnt. Natural fire lines will be made by ploughing up lines across savannahs and sowing them with seeds of quick growing species, such as malota. Broad lines of trees so formed will be invaluable for counterfiring, an impossible operation at present in the large savannahs, and a series of such lines would soon render a savannah barmless. The introduction of forest settlements will considerably minimize the risks from fire, as such settlements cover large savannah areas and afford labour on the spot for extinguishing fires. With the exception of savannahs of almost pure grass the whole area of each of these Working-Circles will be specially protected as described above.

58. Mixed Working-Circles. For the purposes of fire protection these may be split up into two classes (a) grazing grounds and (b) other mixed forest.

(a) The revenue from grazing being more important than the damage done by grazing or fires, areas in which grazing chiefly takes place i. e., Dainah and Jaldáka forest will be burnt as early in the fire season as possible.

In (b) other mixed forests protection from fire will be carried out by the ordinary staff.

59. Boundaries. The external artificial boundaries will be improved by running a shallow ditch along where the line passes through savannah. This will facilitate inspection and render it easy to clear the line year after year. The planting up of these lines with rows of bamboos would, in course of time, do away with the unprofitable expense of line clearing in heavy grass. The replacement of wooden boundary pillars, which are liable to rot, by numbered iron posts should be continued.

CHAPTER V. MISCELLANEOUS.

Section I. Miscellaneous prescriptions.

60. The measurement of trees in sample plots should be continued and, if necessary, more sample plots laid out.

Section 2. Changes proposed in the forest staff.

61. The only change proposed is that the lower class of subordinates should be better paid, in accordance with proposals which have been submitted to Government.

Section 3. Financial results of proposed working.
