1. Introduction

Vision and target for the Black rhino EEP population:

- 1) Ensure a healthy and sustainable EAZA population to fulfil the needs of EAZA zoos.
- 2) Work closely with the African Rhino Specialist Group (AfRSG) and Governments to make Eastern Black rhino available for return to Africa to supplement populations where needed.

All participants must follow the EAZA EEP rules. Especially that all animals and their offspring are available to the EEP. The receiving institution will normally be responsible for the costs of the transfer, unless a pre agreed local arrangement is made between the institutions. It is the responsibility of the sending institution to ensure that the facilities and level of husbandry at the receiving institution are appropriate.

Please note that there are some restrictions on breeding with some individuals. If you have an animal that has a no breeding recommendation, you will have been made aware of it.

Although this EEP focuses on the Eastern subspecies *Diceros bicornis michaeli*, a pair of the Southern African subspecies, *D.b.minor* at Frankfurt Zoo is included within the studbook listings. It should be noted that these two animals are maintained and managed separately to the *D.b.michaeli*.

This studbook report gives an overview of the Black rhino EEP for 2014, including current population, demographic and genetic overviews.

All data and figures used in this report are produced by, or taken from, PMx Version 1.2 and SPARKS Version 1.65.

NB. Frankfurt Zoo holds 1.1 *Diceros bicornis minor*

3. Population Overview

3.1 Current Status

As of 31.12.2014 there were 25.45 (70) Black rhino within the EEP, held in 18 collections.

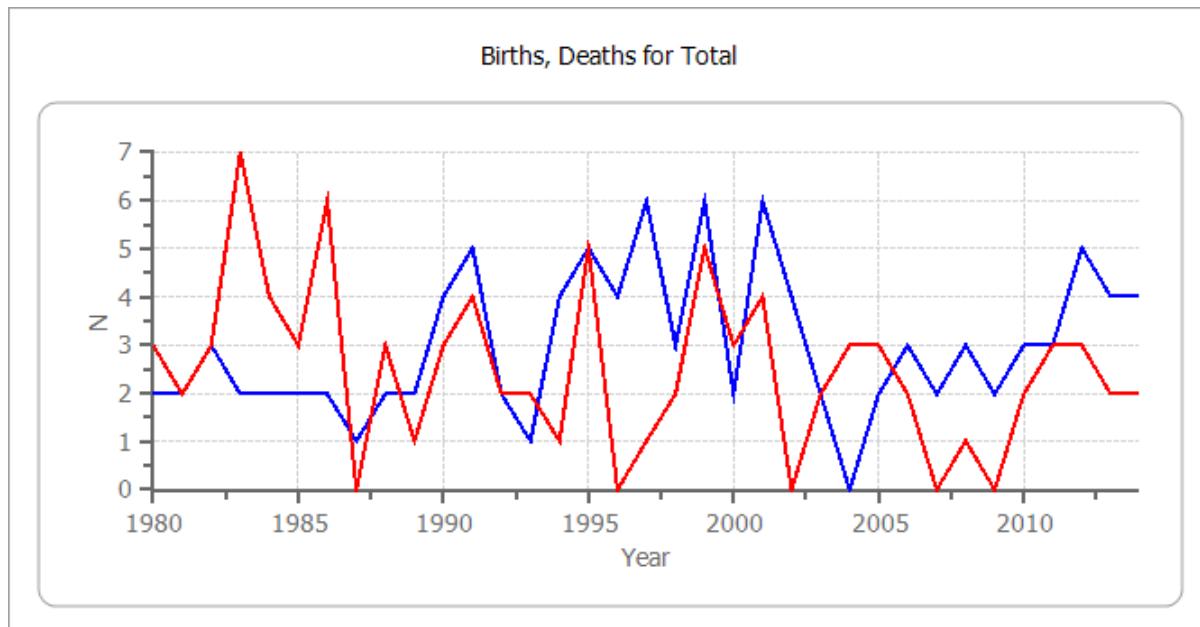

1.1 of these are of the southern subspecies *Diceros bicornis minor* and are held at Frankfurt Zoo. These are included in the demographic, but not genetic analysis of this report.

3.2 Events During 2014

Births – 3.1 births (3 EAZA collections)	
Berlin Zoo	2.0
Leipzig Zoo	1.0
Zurich Zoo	0.1

Deaths – 1.1 deaths (2 EAZA collections)		
Leipzig Zoo	1.0	13 days old
Port Lympne Wild Animal Park	0.1	~44 years old

See Graph 1 for how these rates compare to previous years.

Graph 1: Number of births and deaths per year 2002 – 2014 within the Black rhino EEP.

The following transfers also took place during 2014:

Transfers - 3.2 transfers (4 EAZA collections)	
Hannover Zoo to Chester Zoo	1.0
Leipzig Zoo to Hannover Zoo	1.0
Chester Zoo to Port Lympne Wild Animal Park	1.0
Magdeburg Zoo to Port Lympne Wild Animal Park	0.1
Zurich Zoo to Rotterdam Zoo	0.1

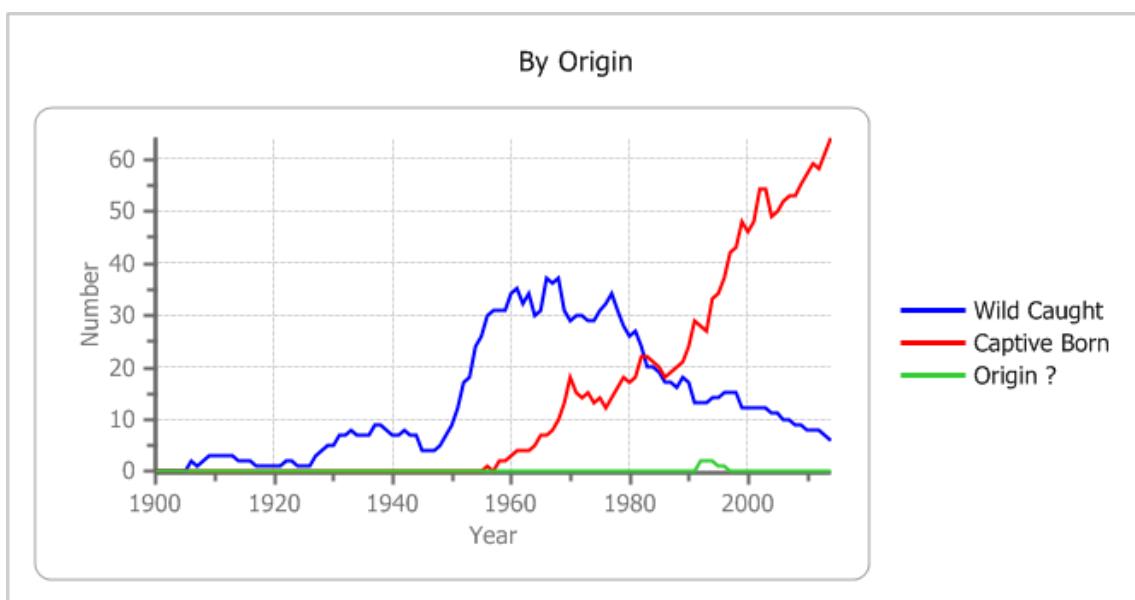

4. Demographic Overview

4.1 Census Graphs

When doing demographic analysis on the Black rhino EEP, we select all animals that were present in the population between 1960 and 2014. This is done using a date filter in SPARKS before exporting data to PMx. Prior to 1960 (shown in Graph 2) the captive population was reliant on wild imports, so the demographic data does not represent what we would expect from a self-sustaining population with natural fluctuation caused by birth and death rates. Indeed, it was not until 1956 that the first Black rhino was born in captivity.

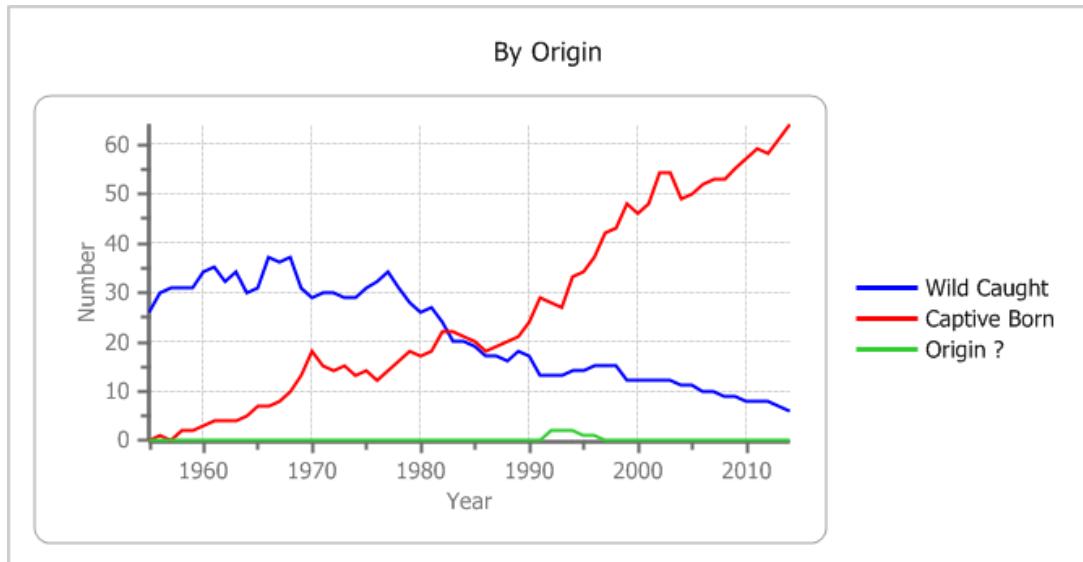

Although 1960 was the very beginning of the captive population shifting towards self-sustainability, and there have been huge advances in captive management since 1960 that may well have affected the population's demographics, we need to select this date as early as possible. It is recommended that the selected time period spans at least twice the life span of an individual, so for such a long lived species the time span selected (54 years) is a minimum of what we need to create demographic projections and predictions.

Graph 2: Census graph of captive Black rhino since 1900 split by origin type – it is not until 1956 that animals are bred in captivity.

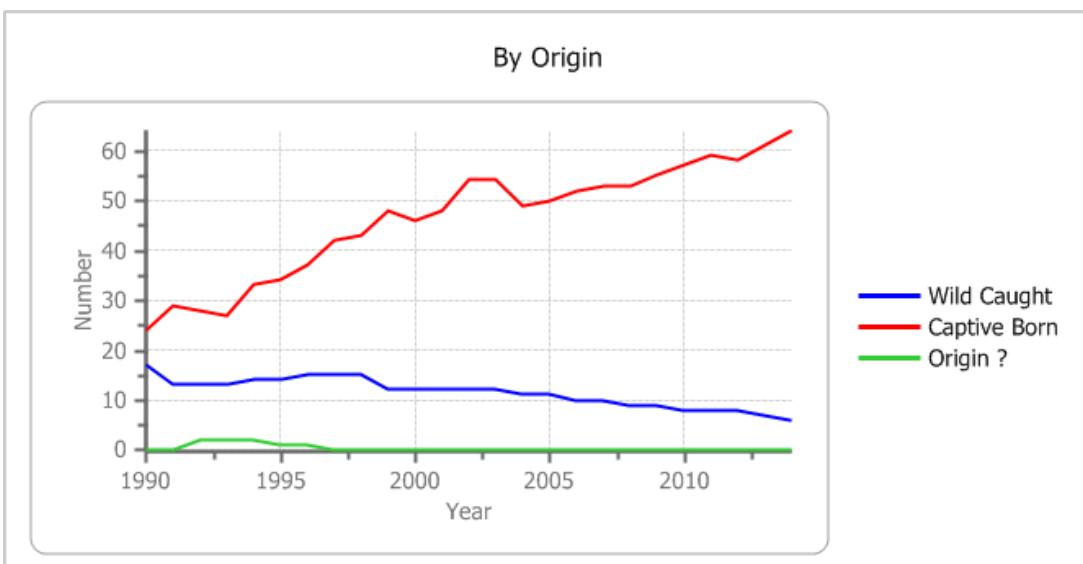

When we look at the census graphs from 1960 until today (Graph 3) we see a steady increase in the captive born population and a decrease in the wild caught animals that die and are not replaced. We can see that the increase in the captive born animals has been quite drastic since 1990 in Graph 4, in fact over doubling in size from 25 to over 65.

Graph 3: There has been a steady increase in the Black rhino captive population since 1955. Census graph here is split by animal origin.

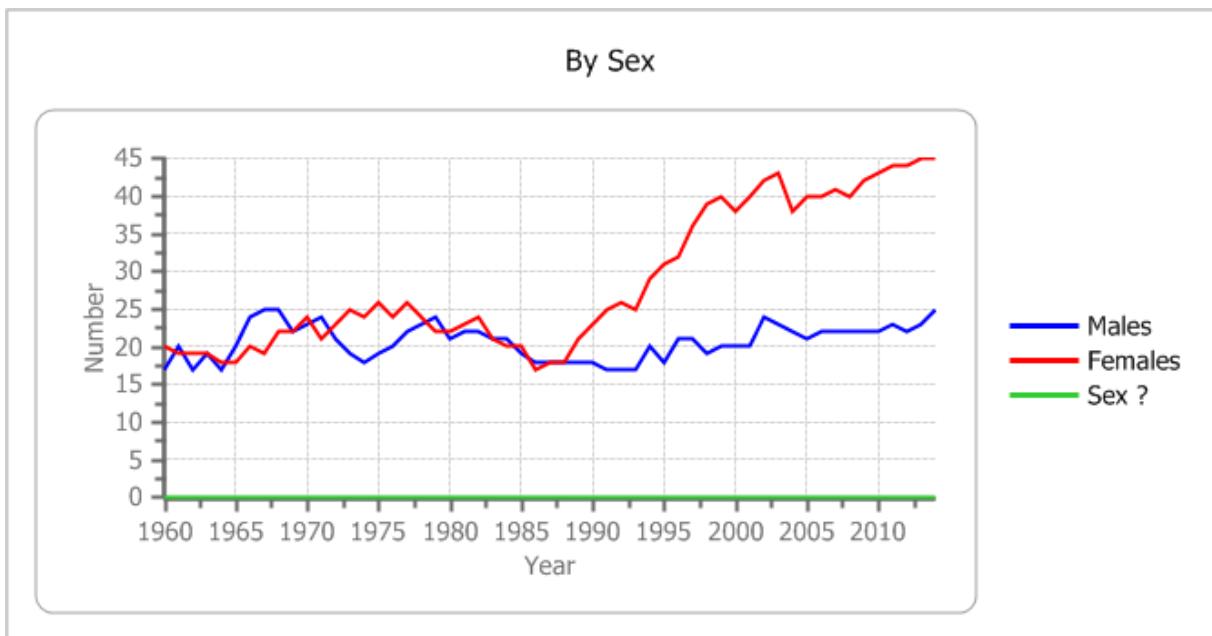

Graph 4: Census graph of Black rhino since 1990 split by origin.

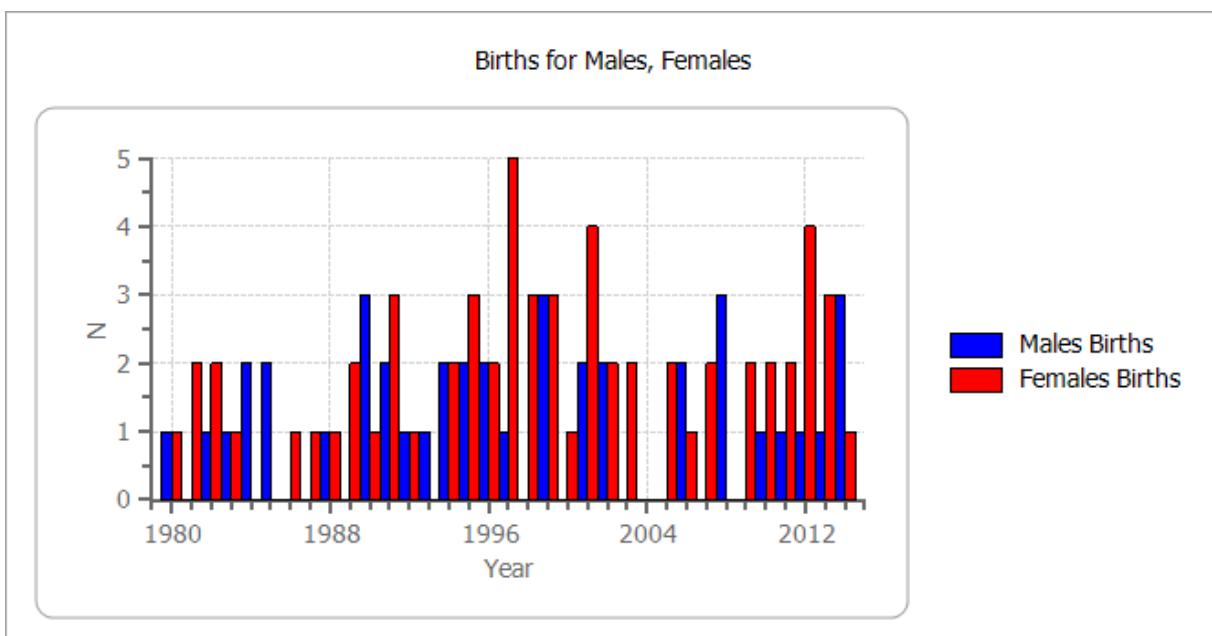

It appears that since 1987 there has been a skew in the sex ratio, with far more females than males in the population (Graph 5). When we look at how many males and females are

born each year since 1980 (Graph 6) we see a slight trend of more females being born, with a total of 62 females born over the last 35 years, but just 41 males. Averages show since 1980 1.2 males were born per year compared to 1.8 females.

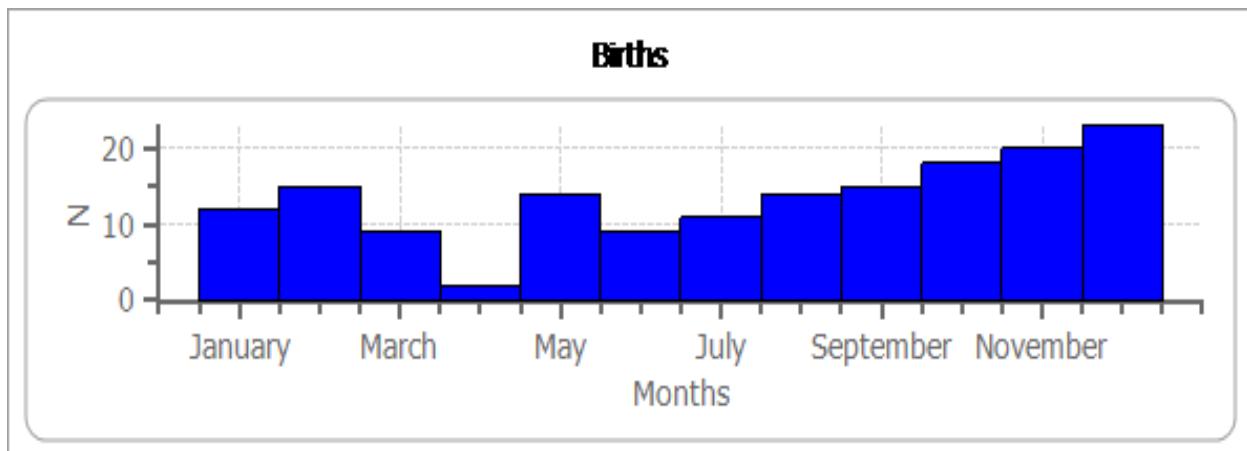

Graph 5: Census graph of Black rhino split by sex.

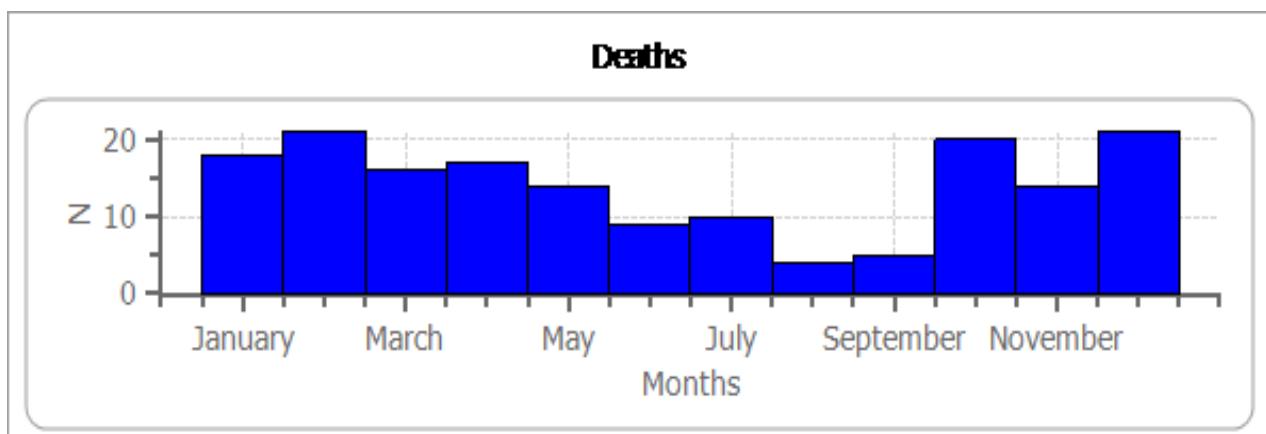

Graph 6: Number of male and female Black rhino born in EAZA collections between 1980 and 2014.

Graph 7: Seasonality of births of Black rhino with EAZA collections.

Graph 8: Seasonality of deaths of Black rhino with EAZA collections.

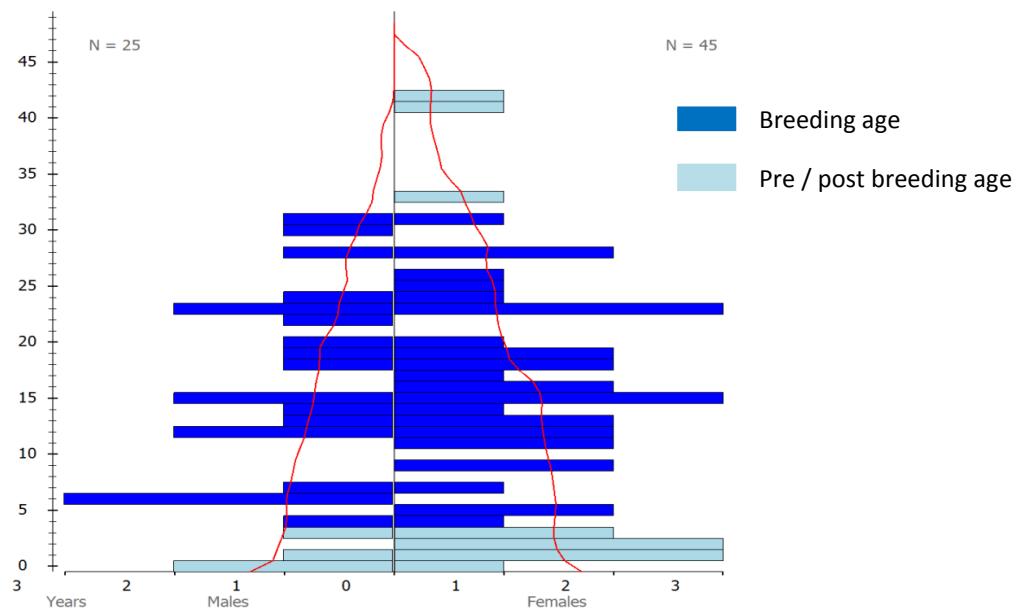

4.2 Age Pyramids

The Age pyramid of the Black rhino EEP population can be seen below (Graph 9). There are 70 black rhinos in the EEP (25.45). The oldest currently living female is 42 years and male is 31 years. The oldest ever recorded female was Kenia who died at Magdeburg in 2013 at ~47 years. The oldest ever male reached the age of 41 years.

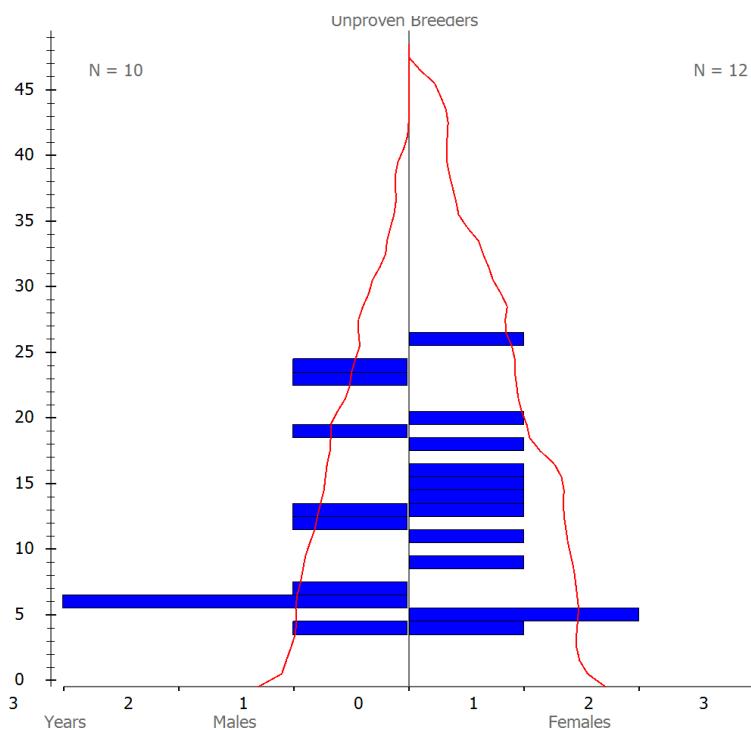

Of the 70 Black rhinos, of breeding age we have 21 males and 33 females. We have 9 pre-reproductive females but just 4 pre-reproductive males. The generation time (time taken from birth to first reproduction) for males is 17.1 years and for females is slightly shorter at 16.4 years.

Currently out of the full 70 only 34 are proven breeders (who have produced one calf, either living or dead). This 34 is made up of 11 males and 24 females. Graph 10 shows the rhinos who are unproven, who have not yet produced one calf.

Graph 9: Age pyramid for the Black rhino population.

Graph 10: Age pyramid for the Black rhino population showing unproven breeders (of breeding age)

4.3 Population Growth and Goals

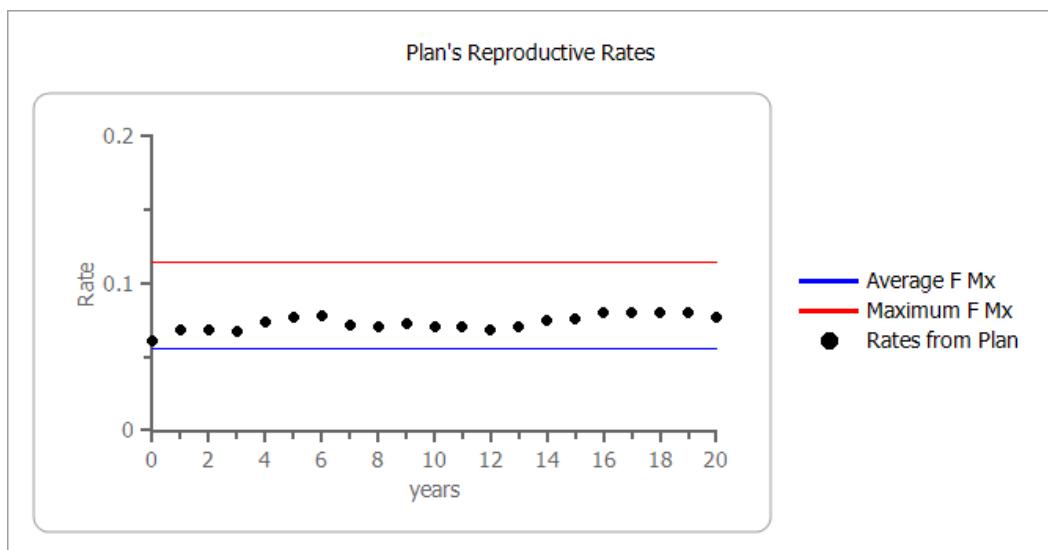

During the time period 1960 – 2014 the lambda, which is the proportional change in population size from one year to the next, based on the life table calculation (expected lambda) averaged for males and females was 0.978. This shows a declining population. But when we look at the population growth rate of 2014, we saw a small increase (lambda from census 1.029) which is positive. If we look at the last three years, we also see a positive lambda of 1.014.

However, after running stochastic projections, taking into account our skewed sex ratio (maximum of 2 females to every one male) we have just a 29% chance of an increase in the population next year (55% chance of decrease and 16% chance of staying the same). PMx predicts that in 20 years if we continue at the average lambda, we will have just 52 rhinos left in the EEP.

We need to increase our birth rate and focus on breeding pairs matched by mean kinship with low inbreeding coefficients. Of course, this is coupled with the drastic need to find new collections to join this EEP. Since 1991, then number of collections participating in the EEP has increased from 10 to the 18 we have today, but we are still struggling for space to place youngsters and move animal around to create important pairings.

In order to maintain our population size of 70 in 2015, we need to achieve 4 births during the year. So we encourage all collections that have a recommendation to breed a specific pair, to make effort to do so. As you can see in Graph 11 below, this reproduction rate is only slightly higher than our average reproductive rate from the last 54 years so should be achievable.

Graph 11: Reproductive rates that must be achieved to maintain a stable population of Black rhino within the EEP.

A full Demographic Summary is shown below:

Demographic Summary	
Size	25.45.0 = 70
Life Expectancy	16.6
30 day mortality	0.15 (N=116)
25% live to	25.7
10% live to	34.6
5% live to	40.6
1% live to	44.6
Oldest living	42.1 (ID:240)
λ	0.978
r	-0.023
R_0	0.685
T	16.8 years

5. Genetic Overview

For genetic analysis, individuals who offer no potential genetic contribution to the future population are removed. The oldest ever recorded female to reproduce was 32 years old, so two animals over the age of 40 (SB# 240 Mzima and SB# 220 Kilaguni at Berlin) are removed. One infertile female is also removed (Manyara at Chester Zoo); as are two individuals at Frankfurt of the sub species *Diceros bicornis minor*. This reduces our managed population to 65 (25.45) living individuals.

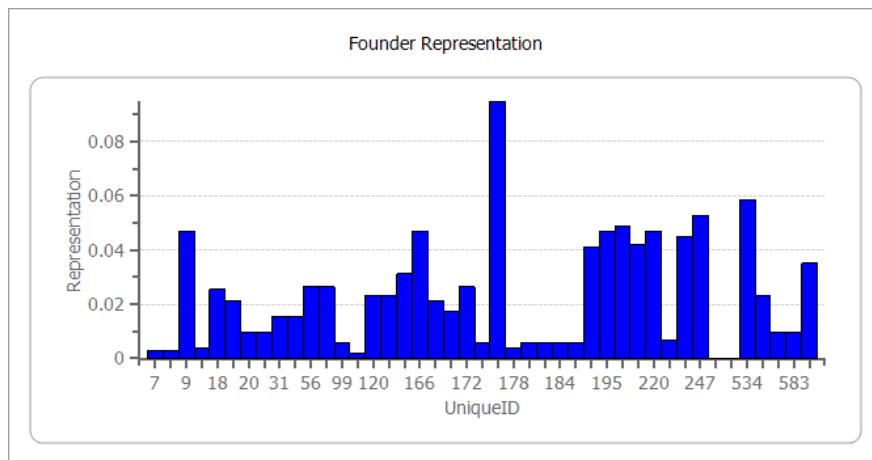

The current living population was founded by 41 animals. These are founders as recorded by SPARKS as those with WILD/WILD parents. This does not include other founders to the EEP population who have been transferred into the EEP from outside Europe and are therefore not related to any other rhinos apart from their offspring. For example Sammy (SB number 750) who came from Osaka, Japan in 1999. The representation of these founders in our living population is shown in Graph 12 below. Of the 41 founders 4 are still alive:

Studbook #	Location	Sex	Age	Descendants	Local ID	House Name
240	Berlin	Female	41	9.0	770025	Mzima
220	Berlin	Female	40	9.0	750016	Kilaguni
558	Lympne	Female	22	3.0	P95039	Vuyu
653	Hannover	Male	21	5.0	400007	Madiba

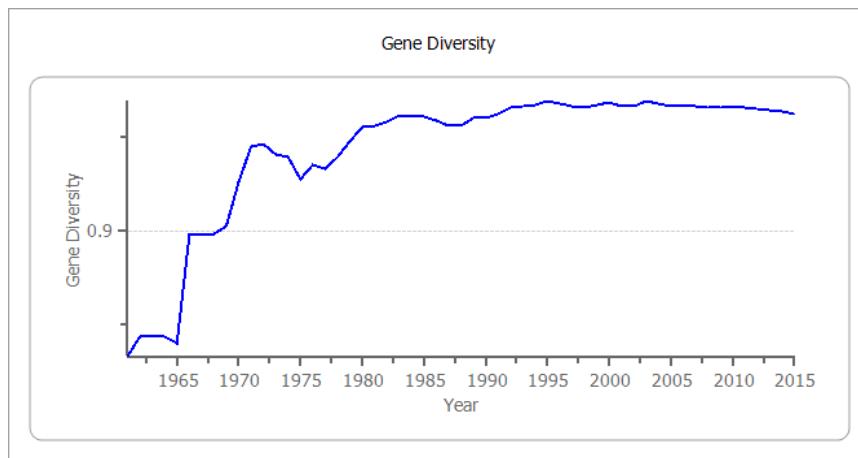

100% of the captive population ancestry is certain, and the genetic diversity of the 65 selected animals (the probability that two alleles from the same locus sampled at random from the population are not identical by descent from a common ancestor) is 0.96 or 96.16%. Graph 13 shows how the gene diversity has changed over time since 1960.

There is a mean inbreeding value of 0.01 (increase from 0.097 in 2013). Graph 14 shows how this has changed over time since 1960. The population mean kinship for the 65 selected animals is 0.0378 (this also shows an increase on last years 0.0366).

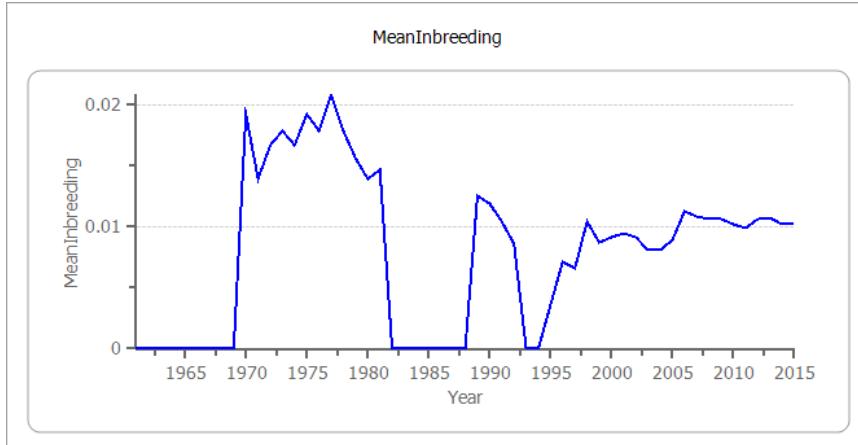

Graph 12: The number of copies of each founder's genes present in the living, descendant population of Eastern Black rhino.

Graph 13: Change in gene diversity from 1960 – 2014 within captive Eastern Black rhino.

Graph 14: Change in mean inbreeding from 1960 – 2014 within captive Eastern Black rhino.

A full genetic summary is shown below:

Genetic Summary	
Founders	41
Potential (additional) founders	0
Living animals	70
Living descendants	64
% Ancestry known	100%
% Ancestry certain	100%
Gene diversity	0.9616
Population mean kinship	0.0378
Gene value	0.9582
Founder genome equivalents	13.22
Founder genomes surviving	20.21
Potential gene diversity	0.9780
Mean inbreeding	0.0103
Ne/N	0.3817

The table below gives us genetic values for each of the 65 individuals included in the genetic analysis, ordered by location. It includes:

- Mean kinship (MK) - the mean kinship coefficient between an individual and all individuals in the living population.
- Mean kinship rank (MK Rank) - a rank of all the mean kinships in the population (1 being the highest)
- Inbreeding coefficient (F) - the probability that the two alleles at a genetic locus are identical by descent from an ancestor common to both parents.

The most important animals to breed are those with the lowest mean kinship value (MK) or the highest (i.e. rank 1) mean kipship rank (MK Rank). Ideally the inbreeding coeficents (F) should be 0. We must also consider age; the oldest animals with the lowest meankinships are genetically the most important due to their reduced time left for breeding.
