

Reassessment of the largest Pleistocene rhinocerotine *Rhinoceros platyrhinus* (Mammalia,
Rhinocerotidae) from the Upper Siwaliks (Siwalik Hills, India)

COMPARISON

Comparison with *Dicerorhinus*

In the Plio-Pleistocene the genus *Dicerorhinus* is represented by two Southeastern Asian species: *Dicerorhinus sumatrensis* and *Dicerorhinus gwebinensis* (Guérin, 1980, Zin-Maung-Maung-Thein, 2008, Antoine, 2012). *Dicerorhinus sumatrensis* differs from the studied specimen NHMUK 36661 in having a smaller size (Table S2), a lesser concave dorsal profile of the skull, an open external auditory pseudomeatus, a posterior border of the nasal notch lying above P2 and an infraorbital foramen lying above the P2-P3 boundary (Table S1; Figs. S1–S2). Moreover, the cheek teeth are low-crowned, the crista and the crochet are usually absent on the premolars, the premolars display a separated protocone and a hypocone, whereas the mediofossette is absent on the molars. The skull of *D. gwebinensis* differs from the studied specimen in having a smaller size, a lesser concave dorsal cranial profile, a posterior border of the nasal notch lying above P2, an infraorbital foramen lying above P2-P3 boundary and in the lack of the mediofossette on M1 (Table S1).

Comparison with *Coelodonta*

Coelodonta is a well-represented taxon in Eurasia and the genus probably originated in the Tibet Plateau during the Pliocene (Guérin, 1980; Deng et al. 2011). The skulls of the species belonging to this genus (Table S1) display an ossified nasal septum (partially in *C. thibetana*) and the presence of an insertion for the frontal horn. Moreover, the posterior border of the nasal notch lies in a more rear position (above P4 or M1) than that seen in the studied specimen as well as the anterior border of the orbit (lying above M2–M3 boundary or above M3) (Figs. S1–S2). In *Coelodonta* the occipital face lying backwards and the occipital crest overhangs the occipital condyles (Fig. S1). The premolars display a closed mediofossette and the metacone fold is absent on the molars (Fig. S2).

Comparison with *Stephanorhinus*

The genus *Stephanorhinus* is closely related to *Coelodonta* and it was widespread in Eurasia during the Pleistocene (Guérin, 1980; Tong, 2012). *Stephanorhinus* has been never reported from the Indian Subcontinent but it has been recorded in southern China (Antoine, 2012; Tong, 2012). The species belonging to this genus (Table S1) are characterized by the presence of a partially ossified nasal septum and of an insertion for the frontal horn (Fig. S1). The upper cheek teeth are less hypsodont than those of the studied specimen, lacking the metacone fold (at least on the molars) (Fig. S2). The mediofossette is rarely observed on M1 and M2. Moreover, the lingual cingulum is usually present on the premolars in *Stephanorhinus* and the metaloph is never ‘S’-shaped in occlusal view (Fig. S2).
